

**A REVISION OF *ARGYROLOBIUM*
(CROTALARIEAE, FABACEAE) IN SOUTH
AFRICA**

by

Trevor John Edwards

Submitted in partial fulfilment of the requirements for the degree of Doctor of Philosophy in the Department of Botany, University of Natal, Pietermaritzburg, 1994.

ABSTRACT

A revision of 45 South African species of *Argyrolobium* is presented comprising nomenclature, typification, recorded distributions and full descriptions. In an attempt to reduce confusion between subtly different species, diagnostic characters are listed and comprehensive illustrations are provided. The dissertation includes numerous taxonomic and nomenclatural changes.

Currently two sections are recognised based on fruit morphology. This is replaced by a system of five new sections based on morphological, micromorphological and phytogeographical evidence.

Constraints and advantages of floral dimorphism and monomorphism are discussed with respect to the fecundity and distribution of sections. It is proposed that the occurrence of facultative cleistogamy in two sections has enhanced their success and distribution.

Generic and specific phylogeny is interpreted using models generated through cladistic methodology.

PREFACE

The experimental work in this thesis was performed under the supervision of Professor J. van Staden and Dr. C.H. Stirton, in the Botany Department of Natal University, Pietermaritzburg, on a part time basis from 1988-1994.

These studies have not been submitted in any form to another University and, except where acknowledged, are the results of my own work.

TREVOR JOHN EDWARDS

Introduction

Chapter 1 Materials & Methods

Chapter 2 Historical Perspectives

Chapter 3 Character Analysis

3.1 Vegetative Characters

 3.1.1 Habit

 3.1.2 Seed & Seedlings

 3.1.3 Leaves

 3.1.4 Leaf anatomy

 3.1.5 Cytology

 3.1.6 Alkaloids

3.2 Sexual Characters

 3.2.1 Inflorescence structure

 3.2.2 Flowers

 3.2.3 Calyx

 3.2.4 Corolla

 3.2.5 Androecium & Palynology

 3.2.6 Breeding systems

 3.2.7 Flowering Times

Chapter 4 Phytogeography

Chapter 5 Conservation

Chapter 6 Cladistics

Chapter 8 Formal Taxonomy

Section *Amplexicaule*

 1. *A. amplexicaule*

 2. *A. crinitum*

Section *Lunare*

 3a. *A. lunare* ssp. *lunare*

 3b. *A. lunare* ssp. *sericeum*

 4. *A. splendens*

Section *Transvaalense*

 5. *A. frutescens*

 6. *A. transvaalense*

 7. *A. muddii*

 8. *A. wilmsii*

 9. *A. megarrhizum*

ACKNOWLEDGEMENTS

The following institutions are thanked for the loan of specimens: B, BM, BOL, BR, C, F, G, GRA, J, K, KEI, LYD, MO, NBG, NH, NY, OXF, P, PRE, S, SAAS, SAM, SRGH, STE, TCD, UNIN, UFH, UPS, W & Z. Special thanks are extended to the staff of the Mary Gunn Library (PRE) and the Life Sciences Library (Natal University) for assistance in tracing literature. Ashley Nicholas is thanked for tracing literature in his capacity as South African Liaison Officer at Kew and for advice on the nomenclature of *A. lunare*. John Rourke, Estelle Brink, Hugh Glen, Pat Lorber, Koos Roux and Gerrit Germishuizen are thanked for tracing the collecting details of *A. rarum*. We are grateful to Nicholas Turland (BM) for photographing the type of *A. lunare*. Roland Momberg is thanked for photographing the Thunberg type material housed at Uppsala and Kew is thanked for the cibachrome copies of their type material.

Natal University is thanked for financial support. The Natal Parks Board, Pietermaritzburg Municipality and the Department of State Forestry are acknowledged for providing collecting permits.

I am indebted to the following people for assistance in the field: Christa Ackermann, John and Sandie Burrows, Wayne Vos, Fanie Venter, Charles Stirton, Neil and Ian Crouch, Art Louw and John Joannou.

My supervisor Prof. J. van Staden is thanked for his support and for proof reading

the thesis. Dr. F.M. Getliffe Norris, who taught me the taxonomic ropes, is gratefully acknowledged.

Special thanks are extended to: Dr. M.T. Smith who assisted me with alkaloid analyses; Dr. R. Beckett and Dr. J. Finnie for computer assistance; Prof. E. Hennessy and Ashley Nicholas for their advise on some nomenclatural problems; Mr. L. Raw and Prof. D. Brothers for advise on cladistics; Mike Lambert for assistance with Latin translations; Christa Ackermann for translating German publications; and the staff of the Natal University Electron Microscope Unit for their assistance.

Finally the support of my family and friends is acknowledged especially: my mother, Gloria Edwards, who kindled my interest, Cheryl Edwards, Christa Ackermann, Miss Rita Gilliland and Alva Wilkens.

INTRODUCTION

This thesis was initiated to overcome problems currently experienced in identifying *Argyrolobium* species. Many of the species concepts currently in use rely on unstable characters such as leaf morphology and indumentum. Other valid specific epithets have not been widely used. This is particularly true of names published by Harms (1899, 1909, 1917) where the type material was destroyed during World War II. Where possible these names are clarified. The last consolidated account of South African species is that of Harvey (1862). Subsequently many species have been described which allow new phylogenetic interpretations of the group. Hopefully this regional revision will augment the work of Polhill (1968) on tropical African species and provide a better understanding of the genus.

Argyrolobium includes approximately 91 species which are distributed from the Cape Province to the Mediterranean and west into the highlands of India. The generic concept was conceived by Ecklon and Zeyher in 1836 and includes facies of other papilionoid genera. This prompted Bentham's comment (1865) that *Argyrolobium* is 'readily known among the Genisteae by the calyx of a *Dichilus* (Crotalarieae) with the corolla nearly that of *Crotalaria* (Crotalarieae) and a pod not unlike some Tephrosiae'. The complete fusion of the staminal sheath further complicates this mélange of characters. Consequently the tribal placement of *Argyrolobium* generated considerable debate (Bentham 1865, Hutchinson 1964, Polhill 1976 & 1981). The controversy was resolved by Van Wyk & Schutte

(1989) who, with the assistance of alkaloid data (Salatino & Gottlieb 1981, Van Wyk *et al.* 1988, 1988a, 1988b, 1989 & 1990a), unequivocally placed the genus within the Crotalarieae. This predominantly southern African tribe includes 15 genera and approximately 1223 species (Van Wyk 1991). South Africa embraces the plexus of diversity in *Argyrolobium*, and its three main allies (*Polhillia*, *Melolobium* & *Dichilus*) are endemic to the subcontinent.

CHAPTER 1

MATERIALS & METHODS

Typification and morphometric studies were undertaken on herbarium specimens from the following institutions (abbreviations from Holmgren *et al.* 1990): B, BM, BOL, BR, C, G, GRA, J, K, KEI, LYD, MO, NBG, NH, NU, NY, OXF, P, PRE, S, SAAS, SAM, SRGH, STE, TCD, UNIN, UPS, W & Z. These studies were augmented with fresh material and field observations where possible. Most of the line drawings were prepared from fresh or spirit material. When herbarium specimens were used for floral investigations flowers were boiled in water and surfactant before being mounted on slides in 50 % glycerine. Where possible 20 specimens were examined from the widest possible geographic range.

Chasmogamous and cleistogamous floral development was investigated using scanning electron microscopy. Fresh buds were critical point dried, mounted on brass viewing stubs and then dissected with insect pins. The dissections were sputter coated with gold palladium for five minutes before being viewed with a Hitachi S-570 S.E.M. at accelerating voltages of 8-10 kV.

Scanning electron microscopy was also used for pollen and vestiture investigations. Anthers were removed from herbarium or fresh specimens of all species. The desiccated thecae were ruptured and the pollen grains were dusted onto brass viewing stubs. These preparations were sputter-coated with gold palladium for five minutes before being viewed at an accelerating voltage of 8

kV. Sections of pollen walls were prepared from fresh pollen fixed within the thecae in 3% glutaraldehyde in 0.05 M sodium-cacodylate buffer for 12 hours. The specimens were then rinsed in two 30 min. washes of 0.05 M sodium-cacodylate buffer. Post fixation was carried out in 2% osmium tetroxide in 0.05 M sodium-cacodylate buffer. Dehydration followed, using 10 min. washes in a graded ethanol series culminating in three washes of 100% ethanol. Specimens were embedded in a graded series of 25%, 50%, 75% Spurr's resin in ethanol, each concentration was maintained for two hours. Finally the specimens were transferred to 100% Spurr's resin for 12 hours. After a change of the final resin specimens were placed into embedding dishes and polymerised at 70° C for 16 hours. The embedded specimens were mounted onto perspex stubs, trimmed and sectioned using a LKB Ultratome III microtome. Sections were mounted on copper viewing grids and stained with 2% uranyl acetate (in darkness) for 15 minutes followed by lead citrate for 15 minutes (Reynolds 1963). Specimens were viewed with a JEOL JEM-100CX T.E.M. at an accelerating voltage of 80 kV.

Free-hand sections were made of the petioles and laminae of most species. These were stained with aqueous Toluidine blue (O'Brein *et al.* 1981) or Fabil (Noel 1964) and mounted in 30% glycerine. In some instances free-hand sections were augmented with resin-embedded sections (method outlined above) which were cut on an ultramicrotome and stained with Ladd's Triple Stain.

Duftmale patterns were revealed by immersing undamaged petals into an aqueous

solution of neutral red for 40 minutes.

Seedling studies were undertaken using field collected seed which was scarified and germinated in petri dishes at 25°C. Vouchers of parent specimens housed at NU.

The character data was transformed into matrices and used in cladistic analysis of the genus. The computer programme Hennig 86 Version 1.5 was used in this study (Farris 1988).

Nomenclatural authorities are given in the formal taxonomy section and are not repeated elsewhere. To avoid cumbersome and repeated explanation the sections recognised in this thesis are outlined below (Table 1).

Table 1. Sections within *Argyrolobium* and their component species.

| Section | Included species |

CHAPTER 2

HISTORICAL PERSPECTIVES

Early classifications placed *Argyrolobium* species in recognised genera such as *Ononis*, *Lotus*, *Cytisus*, *Galega* and *Crotalaria*. Generic status was attributed on four separate occasions. Sweet (1830) recognised the need for generic circumscription of this predominantly African group and he used the name *Tephrothamnus* to describe *Argyrolobium tomentosum* but his generic name was not validly published. The first legitimate generic description is that of Link (1831) who used the name *Lotophyllum* to emphasise the distinction between *Cytisus argenteus* (= *A. linnaeanum* Walp.) and other members of that genus. Five years later, in January 1836, *Argyrolobium* was coined by Ecklon & Zeyher to accommodate 21 new species collected in South Africa. Because of its widespread use, this epithet is conserved over *Lotophyllum* (Greuter *et al.* 1988). Meyer (1836) was simultaneously describing material collected by Drège and he coined the generic epithet *Chasmone*. The synonymy of *Argyrolobium* is outlined in Table 2. Meyer's investigation was submitted for publication in 1835 but was only effectively published in February the following year and consequently *Argyrolobium* holds precedence over *Chasmone*. The confusion over the effective date of publication of Meyer's work led Meisner (1843) to accept *Chasmone* as the generic epithet but subsequent systematists have maintained consensus in their use of *Argyrolobium*.

Superimposed upon this confusion is the recognition of different generic limits for *Argyrolobium*. Thus, for a brief period, the names *Gamochilum* and *Trichasma* were used (Walpers 1839). These generic concepts were based on differences in the degree of sinus development between the calyx lobes. However due to inconsistency in this character the genera were reunited with *Argyrolobium* (Jaubert & Spach 1843).

Sectional subdivisions of the genus have been limited by an inadequate knowledge of African species. The system of Jaubert & Spach (1843) recognised two series based on leaf morphology. Series *Homophylla* is characterised by equal leaflets within a single leaf while series *Heterophylla* has oblique to dimidiate lateral leaflets. The first series includes six sections and the latter includes two, together these embrace 12 species. Their enumeration covers only five southern African species, under the subheading '*Species Capensis*', and does little to define infrageneric groupings. Bentham (1844) attempted to redress this problem by subdividing *Argyrolobium* into two sections based on fruit structure. His section *Eremlobium* Benth. is highly disjunct, linking North African species with *A. lunare*, of the Cape, based on torulose fruits. The second section was named *Chasmone* (E. Mey.) Benth. Harvey (1862) adopted Bentham's sections in Flora Capensis and subdivided the typical section into six informal categories. Of these *Involucrata* Harv. *nom. nud.* has been awarded generic status as *Polhillia* (Stirton 1986) and some of the remaining groups are natural and have been retained in our

circumscription of sections.

CHAPTER 3

CHARACTER ANALYSIS

Morphometric data are presented in the formal descriptions and are not repeated in this section.

3.1 Vegetative Characters

3.1.1 Habit

Within most groups of plants there is a critical interplay between habit and biogeography. In the Genisteae s.l. (Polhill 1976) there are two basic trends. The first is towards perennial stems and persistent leaves, the second is towards ephemeral stems which grow rapidly but which do not persist under adverse conditions. Implicit to the latter is the subterranean proliferation of organs i.e. rhizomes, caudices and lignotubers common in plants associated with seasonal climates and frequent fires. The destruction of aerial parts removes apical dominance and may result in the rapid extension of dormant buds from the base of the stem (James 1984). Between these extremes there exist intermediate herbaceous taxa.

The polarization of lignotubers is problematic, in terms of phylogeny (Stirton 1989). In the Cape flora resprouting is considered plesiomorphic and reseeding apomorphic (Keeley 1977). *Indigofera* follows this trend with reversal to a woody habit in sections *Brevipatentes*, *Spinosae* and *Hispidae* (Schrire 1991). Interpretations of plant habit however often presume that woody correlates to

primitive (Harvey 1862; Dümmen 1913; Polhill 1981). In *Crotalaria* primitive species tend to be forest marginal shrubs of afromontane regions and the invasion of savanna and grassland was accompanied by a shift to herbaceous and suffrutescent habits (Polhill 1982). Similarly in *Lotononis* the occurrence of lignotubers is derived and has arisen independently in a number of lineages (Van Wyk 1991). Most species of *Argyrolobium* are suffrutescent with new stems being produced from persistent, woody rootstocks. Some of these species have weakly perennial stems which persist and become moribund in the absence of fire or grazing, others produce annual stems from lignotubers (Table 3). A third group, concentrated in the eastern Cape, comprises woody shrubs.

In the tropics shrubby and large suffrutescent species are associated with temperate vegetation and persist as spreading shrubs in situations not affected by fire but behave as suffrutescences in more seasonal environments i.e. *A. macrophyllum* Harms and *A. fischeri* Taub. Other species such as *A. friesianum* Harms and *A. tomentosum* tend to be limited to evergreen afromontane vegetation. An unusual situation occurs in *A. wilmsii* where leaf and stem senescence is often asynchronous with flowers being borne on defoliated plants.

Table 3. Various combinations of habit characters in species of *Argyrolobium*. Basic groups are indicated. WP = weakly perennial; A = annual; P = perennial; L = lignotuber; W = woody rootstock; H = herbaceous; SF = suffrutescent; S = shrub.

| GROUP & SPECIES | STEM PERSISTENCE | ROOTSTOCK | HABIT |

A number of repetitive character combinations occur with respect to habit (Table 3). Herbaceous species with weakly perennial stems (Figure 1) are common in savanna and grassland (Group 1) and one lineage within this group has developed lignotubers (Group 1a).

The larger, suffrutescent species with annual stems (Group 2) also occur in seasonal savanna and grassland but they are limited to areas of summer rainfall and appear to have developed lignotubers convergently with Group 1a. Suffrutescent species with perennial stems are common in the Transvaal and are associated with woodland habitats (Group 3). This growth form is reminiscent of many mesic *Crotalaria* species.

Shrubby *Argyrolobium* species are exclusive to the Cape fynbos and associated vegetation types (Group 4). Shrubs have evolved convergently in sections *Argyrolobium* and *Polyphyllum*.

Stem posture follows similar trends to the groups outlined above. Most of the weakly perennial species are procumbent or decumbent. Species with lignotubers (Groups 1a & 2) and shrubby species (Group 3) are erect.

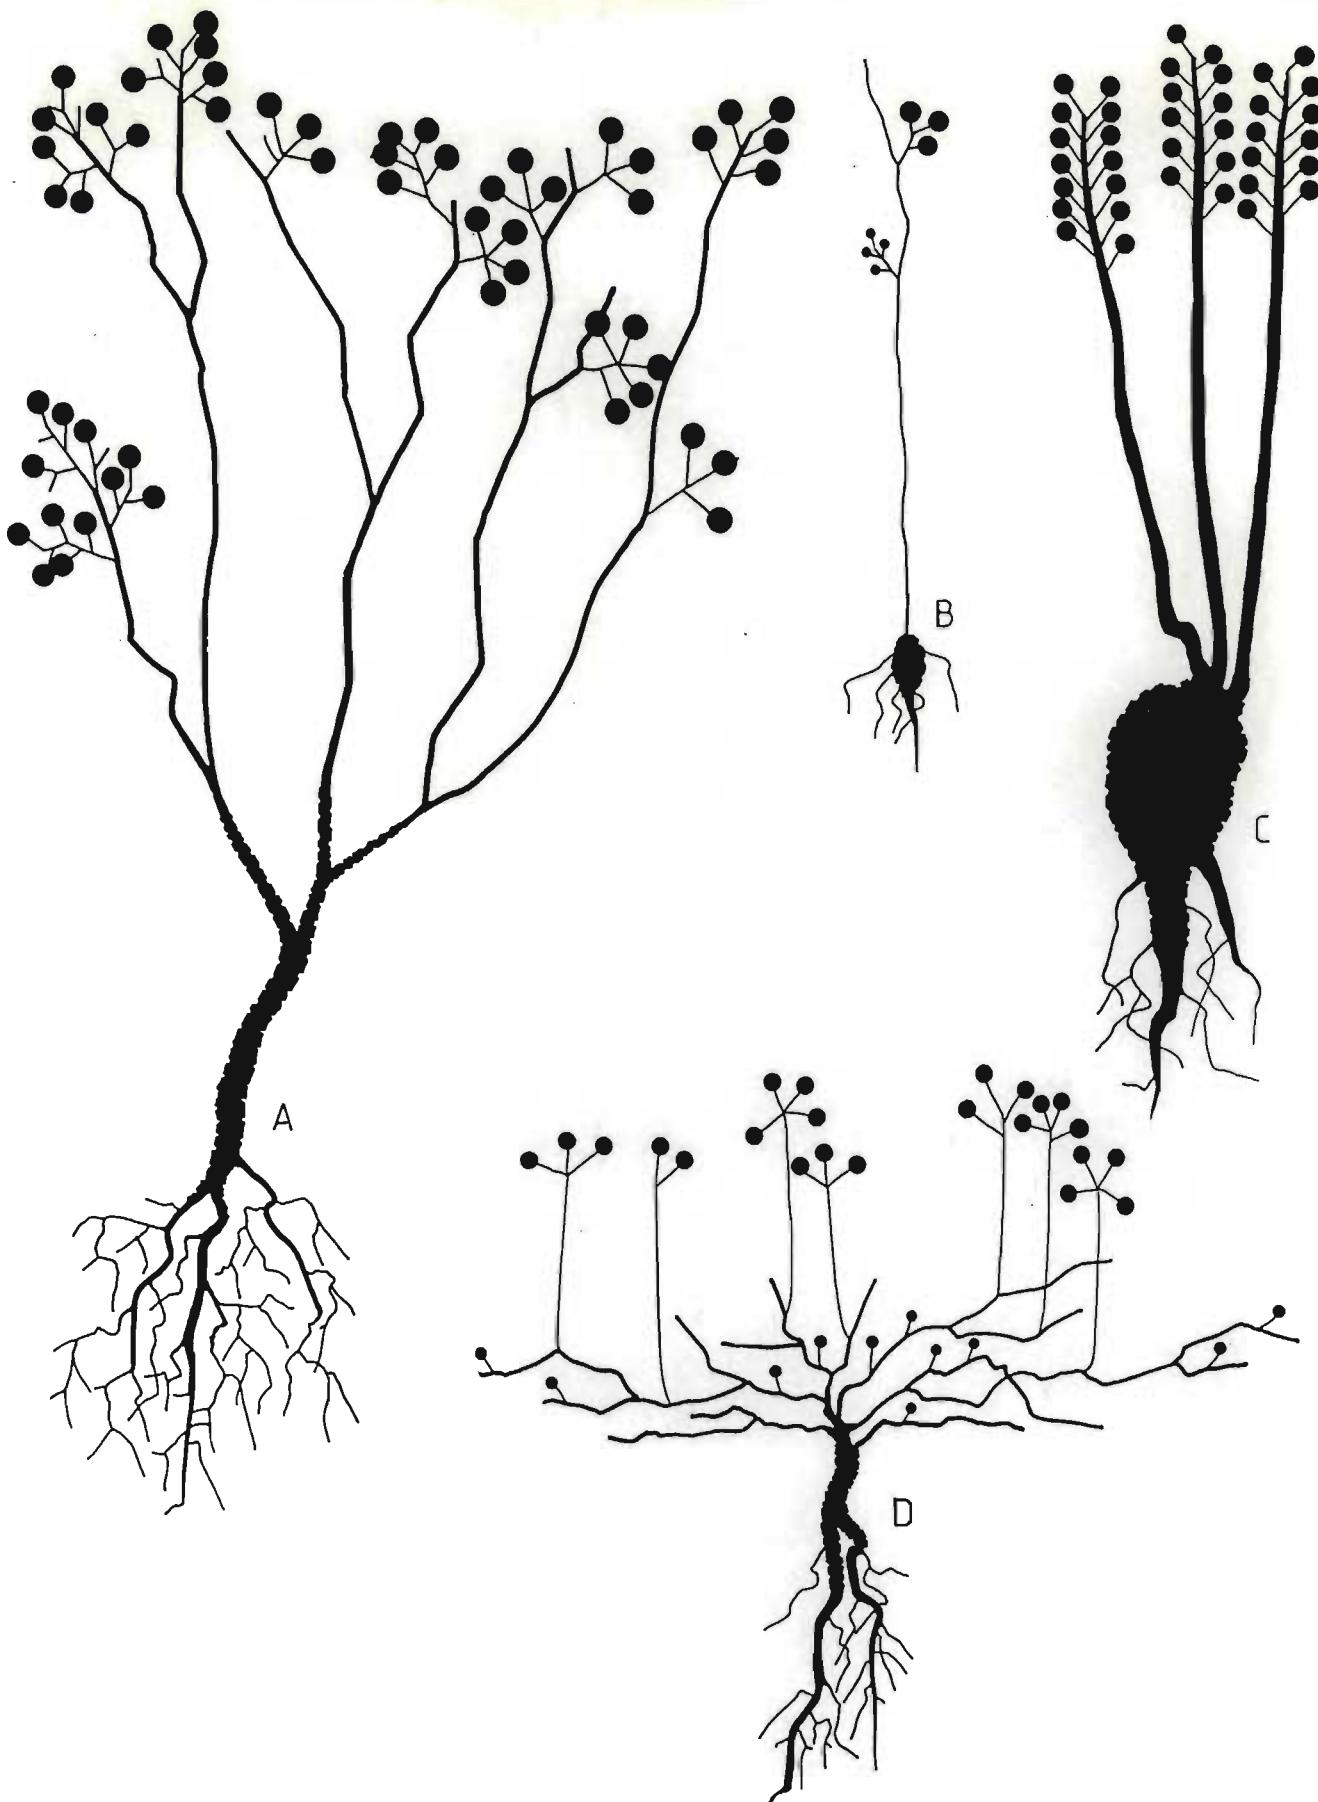

Figure 1.

Habit diagrams of *Argyrolobium*. A. Perennial shrubs, flowers monomorphic; B. perennial herbs with lignotubers, flowers dimorphic; C. suffrutescences with annual stems, flowers monomorphic; D. perennial herbs, flowers dimorphic (small circles).

The polarisation of habit within *Argyrolobium* is not clear. It would be simplistic to assume that the group follows the trend common in the subfamily because the woody species (Group 4) that occur in the Cape appear to be secondarily derived. From their unspecialized nature and relictual distribution, perennial suffrutices (Group 3) and weakly perennial herbs (Group 1) appear to represent the plesiomorphic state. This polarisation complies with a tropical origin for the genus.¹

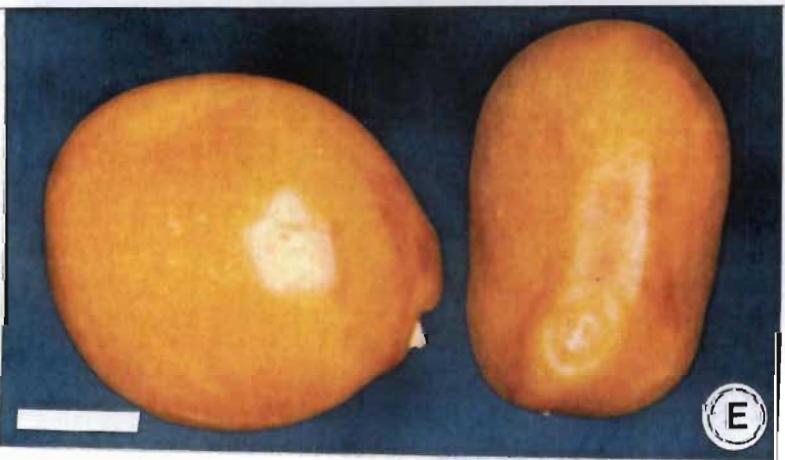

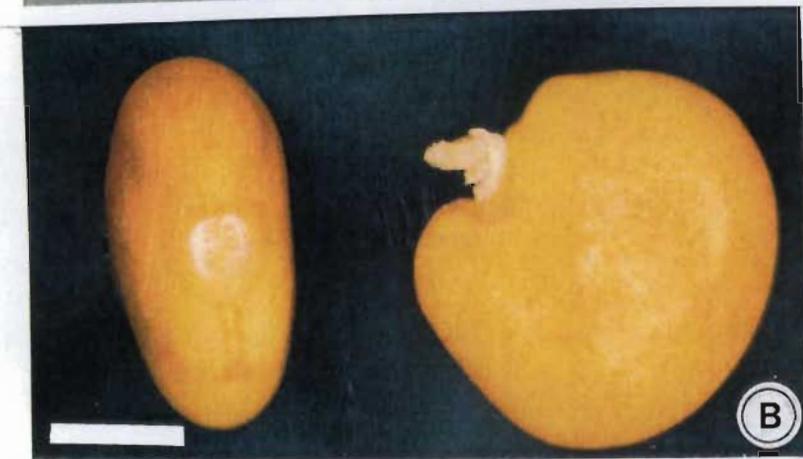

Bark

Stirton (1989) reports the presence of three bark types in the genus *Otholobium*. Some species display a thin phellem with scattered lenticels and photosynthetic stems. This bark type is also common in members of the Crotalarieae. His second bark type is a modification of the first. Here green tissues lie beneath a thin, ephemeral phellem which is not perforated by lenticels. The third bark type is common in species of seepage areas with many, filed lenticels.

Within *Argyrolobium* three bark types have been observed but these do not conform to those of *Otholobium*. Species of moist environments such as *A. polyphyllum* have thin phellem with scattered lenticels overlying photosynthetic tissue. Shrubby species of fynbos and Karroo vegetation have thicker phellem but

Figure 1.

Habit diagrams of *Argyrolobium*. A. Perennial shrubs, flowers monomorphic; B. perennial herbs with lignotubers, flowers dimorphic; C. suffrutices with annual stems, flowers monomorphic; D. perennial herbs, flowers dimorphic (small circles represent cleistogamous flowers).

A. collinum, *A. filiforme*, *A. harveyanum*, *A. incanum*, *A. longifolium*, *A. lotoides*, *A. marginatum*, *A. molle*, *A. polyphyllum*, *A. pumilum*, *A. rotundifolium*, *A. rupestre*, *A. sericosemium*, *A. speciosum*, *A. tomentosum*, *A. tuberosum* and *A. wilmsii*.

Within the genus seedling morphology approximates that of adult plants. Germination is always epigeal which conforms to the pattern of the Crotalarieae. The cotyledons are photosynthetic, amphistomatous and suborbicular in all *Argyrolobium* species examined.

Where dimorphic leaves occur in adult specimens, seedlings have broad leaflets with pronounced petioles and stipules which approximate the morphology of the lower leaflets of adult plants. This includes: *A. baptisioides*, *A. harveyanum*, *A. longifolium*, *A. molle*, *A. polyphyllum*, *A. speciosum* and *A. tuberosum*.

In some species with monomorphic shortly petiolate leaves (*A. stipulaceum*, *A. amplexicaule*, *A. collinum*) the first leaves have pronounced petioles.

Seeds of *Argyrolobium* are fairly conservative in structure. They are often irregular shapes due to constraints imposed by the fruit wall and adjacent seeds. The development of the radicular lobe is variable but especially pronounced in *A. tomentosum* (Figure 2). The development of the hilar tongue (Manning & Van

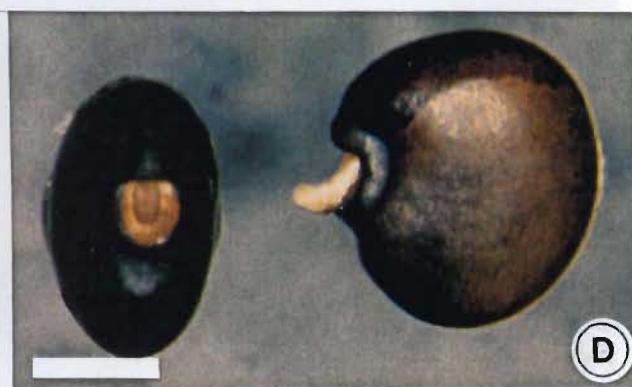

Staden 1987) is also variable within the genus but is usually present. In *A. ascendens* the hilar tongue is superseded by a rim-aril (Figure 3).³

The position and form of the micropyle in relation to the aril was considered phylogenetically important by Manning & Van Staden (1987) who interpret crotalariaoid micropyles as punctate and phylogenetically advanced. This condition is merely the result of the ypsiloid aperture being slightly recessed (Figure 4). Within *Argyrolobium* the micropyle is constantly ypsiloid and recessed, positioned just outside or within the hilum (Figure 5).

Seed colour is seldom consistent within species, ranging from red-brown through yellow-brown and green-brown to black (Figures 2 & 3). The testa may be evenly coloured but in many species speckling also occurs. Freshly harvested seed is often yellow but usually darkens to various shades of beige or brown. Because of its instability this character has not been used in taxonomic assessments. Seed size is variable, some of the herbaceous perennial species produce small seed while the shrubs and large suffrutices usually produce large seeds. Seed masses from cleistogamous and chasmogamous flowers harvested simultaneously and kept in

Figure 3.

Stirton (Burgers 3238); J. *A. ascendens* (Edwards 506). Bars = 1 mm.

identical moisture regimes do not differ significantly for individual plants.⁴

3.1.3 Leaves

Stipules are common throughout the Crotalarieae and are sometimes diagnostic.

The genera *Lotononis* and *Rothia* are distinctive in possessing single stipules.

Unfortunately stipule number is frequently variable across taxa and Van Wyk (1991) recognises seven different conditions within *Lotononis* which he polarises as follows:

Type A. Paired, symmetrical - Plesiomorphic

Type B. Paired, asymmetrical - Intermediate

Type C. Variable - Apomorphic:

C1. Paired basally, solitary above

C2. Usually absent but present at some nodes

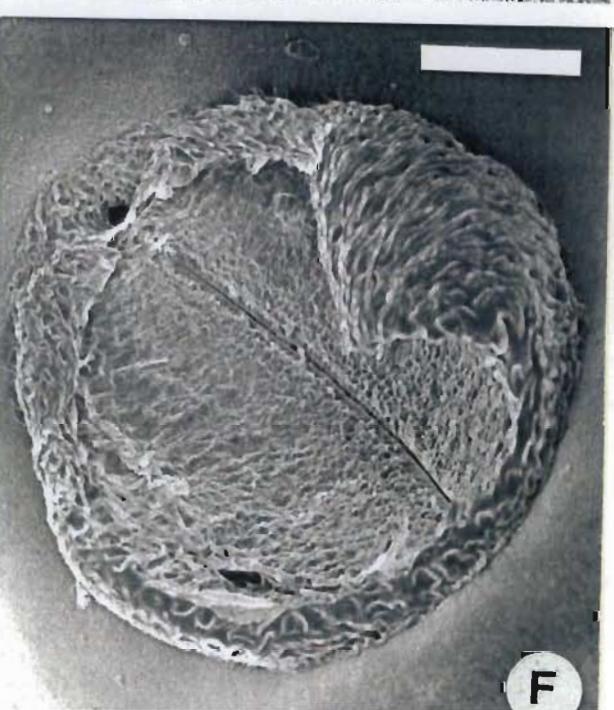

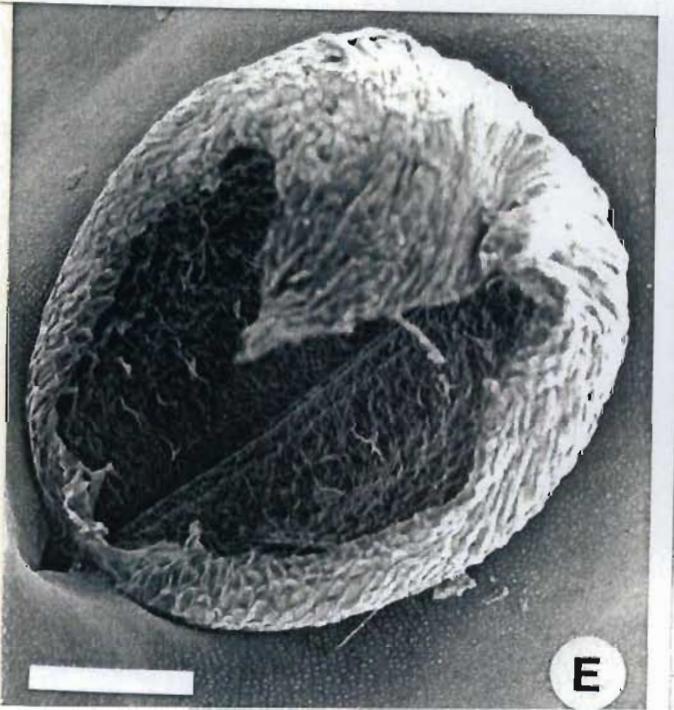

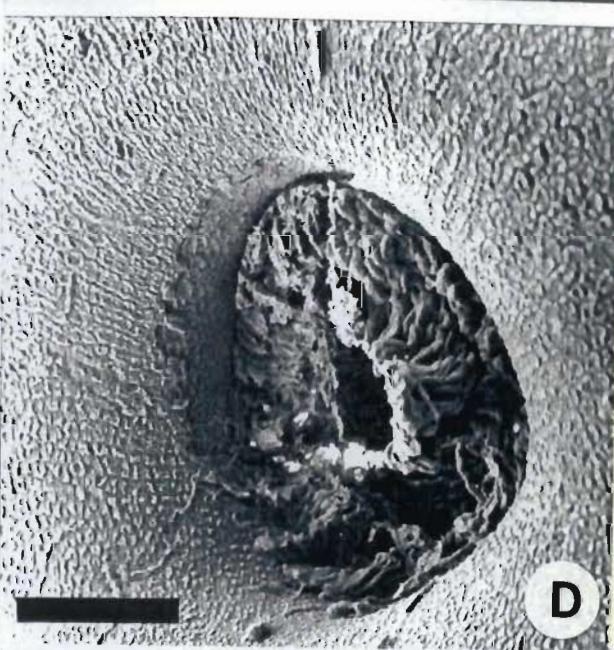

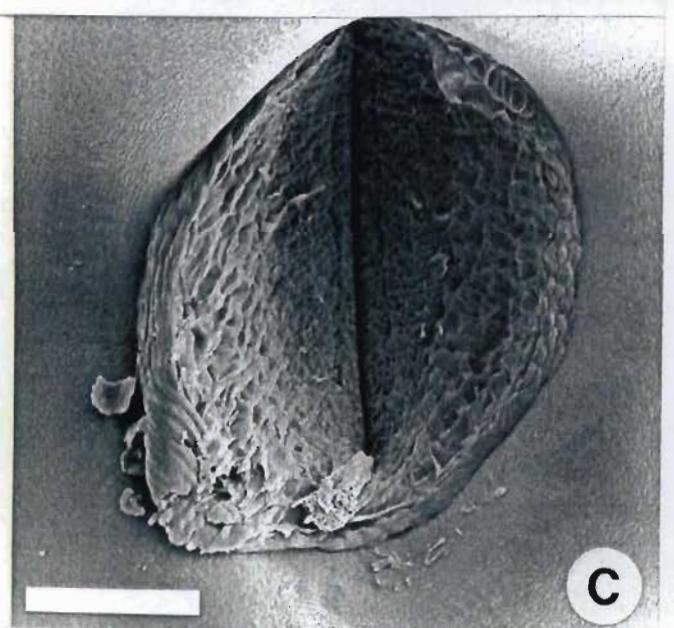

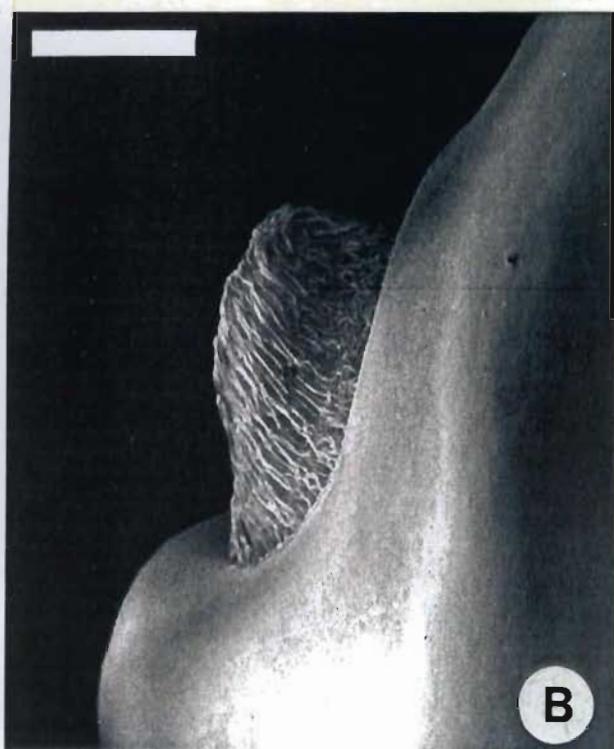

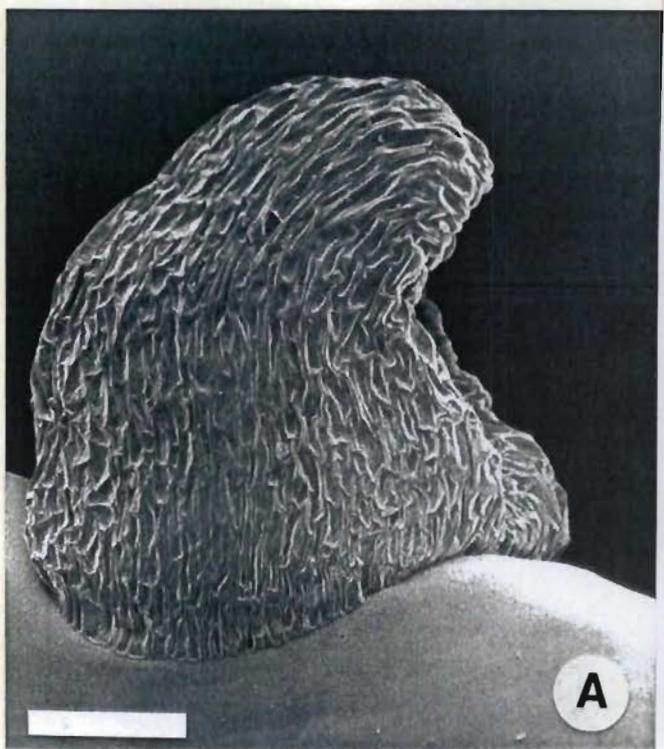

C3. Stipules digitate

Type D. Single at all nodes - Apomorphic

Type E. Exstipulate - Apomorphic

Figure 4.

Hilar views of selected *Argyrolobium* species: A. *A. ascendens* aril, lateral view (*Edwards* 506); B. *A. sericeum* hilar tongue, lateral view (*Edwards* 337); C. *A. collinum* hilum showing counter palisade and hilar tongue (*Edwards* 481); D. *Polhillia canescens* hilum occluded by funicle remnants (*Burgers* 3238); E. *A. stipulaceum*, micropyle ypsiloid and outside the hilum (*Edwards* 433); F. *A. sericeum* hilum, micropyle 'punctate' and within the hilum (*Edwards* 337). Bars A, C, E, F = 100 µm; B = 150 µm; D = 70 µm.

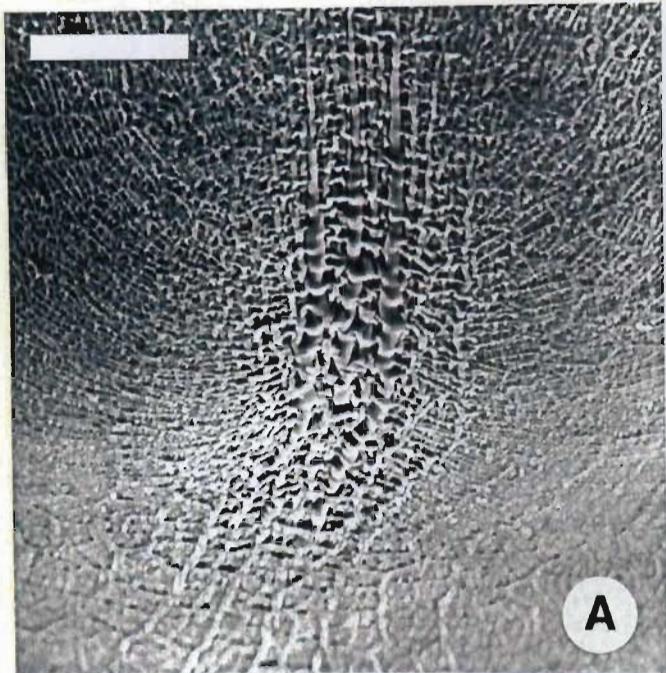

Within *Lotononis* the various stipular states have arisen more than once. A similar situation occurs in *Crotalaria* where all the sections outlined by Polhill (1982) display more than one condition, indicating discrete derivation.

The broad-based, connate stipules of *Polhillia* are a strong linking character with *Argyrolobium*. However adnation of the stipules and petioles in *Argyrolobium* (now *Polhillia* spp.) and *Lupinus*, which was considered autapomorphic by Hutchinson (1964), is clearly convergent based on holistic evidence.

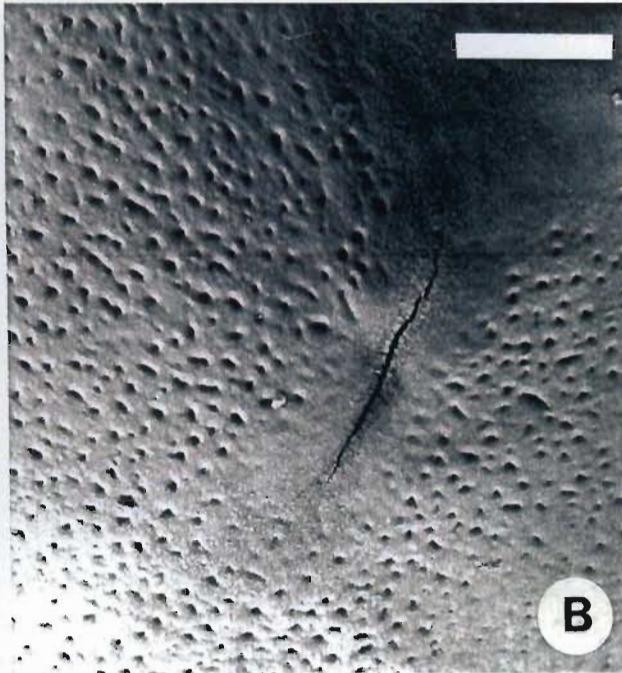

Argyrolobium always has two stipules per leaf. In *A. amplexicaule* and *A. crinitum* these are enlarged and fused along their leaf-opposed margins however their derivation is clear from the venation patterns and 2-lobes in *A. amplexicaule* (in *A. crinitum* the stipule apices are often 4-lobed) (Figure 6). This character grades into the remaining species through partial fusion in *A. campicola*, *A. barbatum* and *A. sericeum* (Figure 6). In addition the fusion of cataphyllous stipules is common in most species at, and below, ground level.

Figure 5.

A

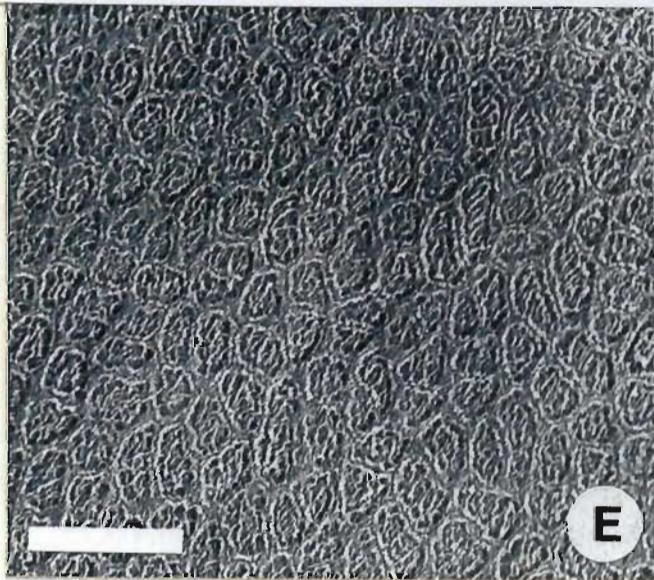

B

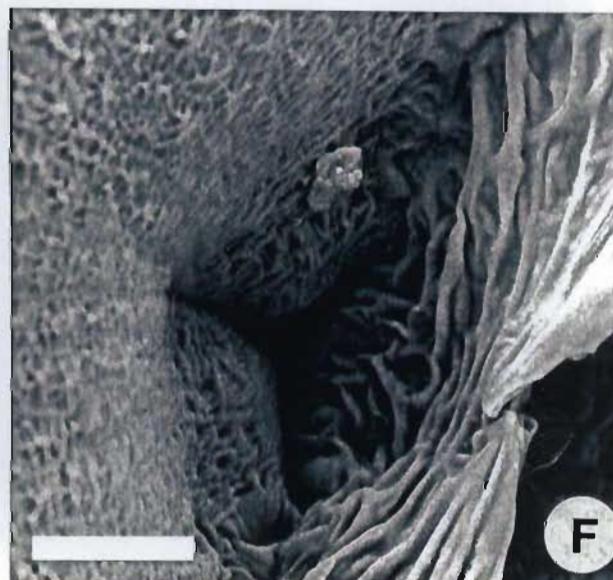

C

D

E

F

Prominent stipules are usually slightly asymmetrical about the midvein and this is accentuated in the Cape species *A. splendens* and *A. lunare* (Figure 6). The large suffrutescent species with annual stems have erect stipules of varied morphology. In *A. speciosum* and *A. baptisioides* stipules are often large but in the remainder of these species stipules are smaller and are sometimes vestigial in *A. megarrhizum*.

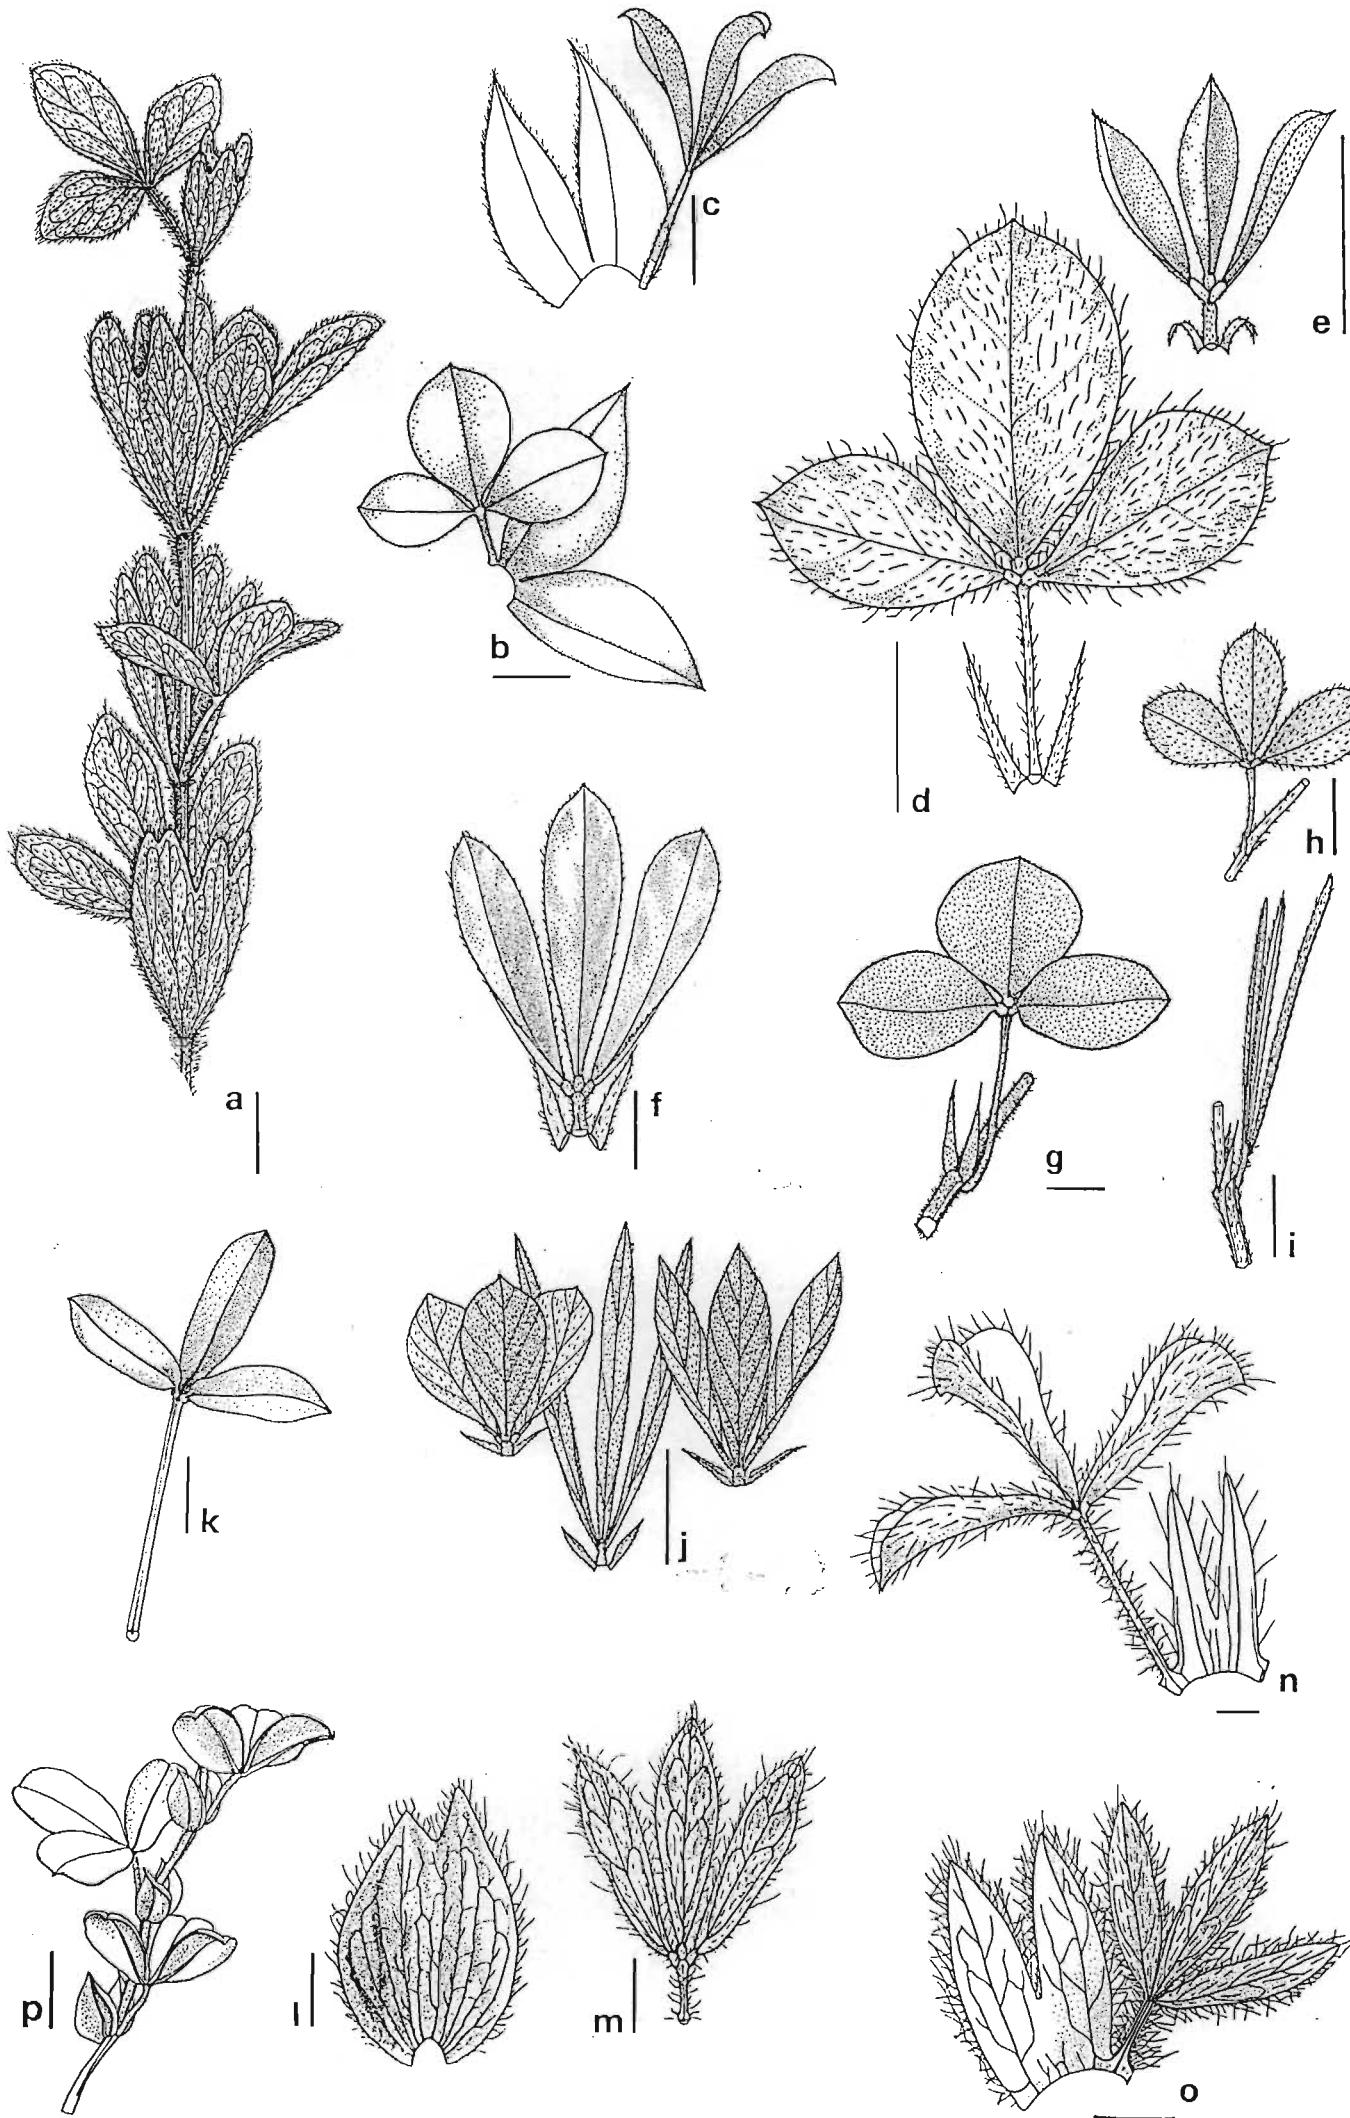

Most *Argyrolobium* species with enlarged stipules have annual or weakly perennial stems and the increased photosynthetic area provided by these organs enhances seasonal growth. This strategy is especially important at high altitudes where favourable growing periods are contracted. The increased transpiration associated with enlarged stipules restricts such species to areas of high rainfall (Figure 7). Reduction and expansion of stipules are considered apomorphic and the intermediate condition, present in tropical species, is considered plesiomorphic.

Leaf dimorphism is common in erect species of *Argyrolobium* where light intensity and air humidity are modified by surrounding vegetation. In extreme cases the lower leaflets are orbicular with well developed petioles and the upper leaflets are linear and subsessile. The extent of dimorphism is strongly influenced by shading so that under uniform light regimes leaf dimorphism is minimal. This variability in expression of leaf shape has led to considerable confusion in the species concepts of *A. tuberosum*, *A. harveyanum* and *A. molle*.

Developmental dimorphism has also been recorded from the genus and in these instances the seedling leaflets approximate leaves from the lower stems of adults. Leaf dimorphism is prominent in species with annual or weakly perennial stems and lignotubers however it also occurs in the shrubs *A. polyphyllum* (Figure 6) and *A. trifoliatum*. Leaf dimorphism has not been recorded from suffrutescent species with perennial stems and appears to be apomorphic.

Petiole development is important in distinguishing a number of closely related species of *Argyrolobium*. Within the *A. rupestre* alliance the procumbent species (*A. rupestre* and *A. rotundifolium*) have well developed petioles but erect and decumbent species have very reduced petioles (*A. humile* and *A. ascendens*). This character is remarkably stable and has therefore been used in distinguishing species. Petioles of some fynbos species are also pronounced (*A. argenteum*, *A. petiolare*, *A. lunare*, *A. rarum* and *A. splendens*).

Leaf vestiture has been used extensively in the taxonomy of *Argyrolobium* and has caused confusion in species delimitation. Vestiture is unstable with frequent variation in single specimens. The role of plant vestiture is a dynamic one related to protection from phytophagous insects, protection from high light intensity and reduction in transpiration (Woodman & Fernandes 1991). Both the environment and the age of leaves influences their vestiture with hair density decreasing with age due to abrasion and leaf expansion. Moderate densities are found to be most

efficient in reducing predation (Goertzen & Small 1993; Levin 1973; Schoener 1987; Woodman & Fernandes 1991). This pattern also occurs in *Argyrolobium* although quantitative measurement was beyond the scope of this dissertation.⁶

Trichomes in most *Argyrolobium* species accumulate tannins which complement the tanniniferous epidermal cells common throughout the genus. Their increased occurrence along leaf margins in most species may deter edge-feeding insects. In species where trichomes are sparse or absent from the adaxial leaf surfaces, tanniniferous epidermal cells are abundant.

Glabrescent species such as *A. harveyanum* var. *nigrescens*, *A. speciosum* and *A. baptisioides* often turn black on exsiccation due to accumulated phenolics which may usurp the anti-predatory function of tannin-containing trichomes.

Figure 6.

3.1.4 Leaf anatomy

Leaf anatomy was investigated where fresh material was available. Methods of fixation and resin embedding are covered in Chapter 1.

Sections of petioles were made and most species have three distinct vascular traces which, in some instances, are maintained for the length of the petiole. In species with subsessile leaves (*A. collinum*, *A. ascendens* and *A. humile*) the vascular tissue usually forms single traces but the abaxial fibres are randomly subdivided into numerous groups. In all species examined the parenchyma, above the bundles, had thickened walls which may represent the vestiges of fibre development.

Lamina anatomy was examined in a number of species and displayed consistent trends. In most species the abaxial leaflet vestiture is pronounced and leaf anatomy is dorsiventral. This correlates to the distribution of stomata, which predominate on the lower surfaces and the occurrence of tanniniferous cells in the upper epidermis. Canescent species such as *A. collinum*, *A. candicans*, *A. incanum* and *A. stipulaceum* are amphistomatous and isobilateral, with tanniniferous cells in the upper and lower epidermis. Discolorous species such as *A. pumilum*, *A. rotundifolium* and *A. trifoliatum* are hypostomatous and tannins are usually restricted to the upper epidermis.

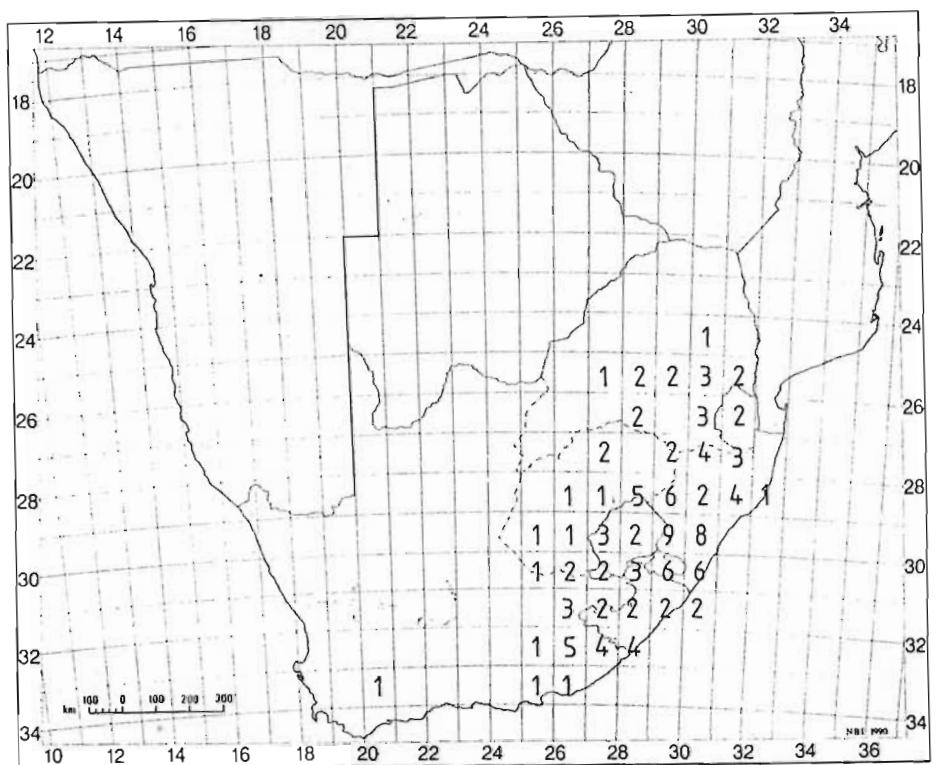

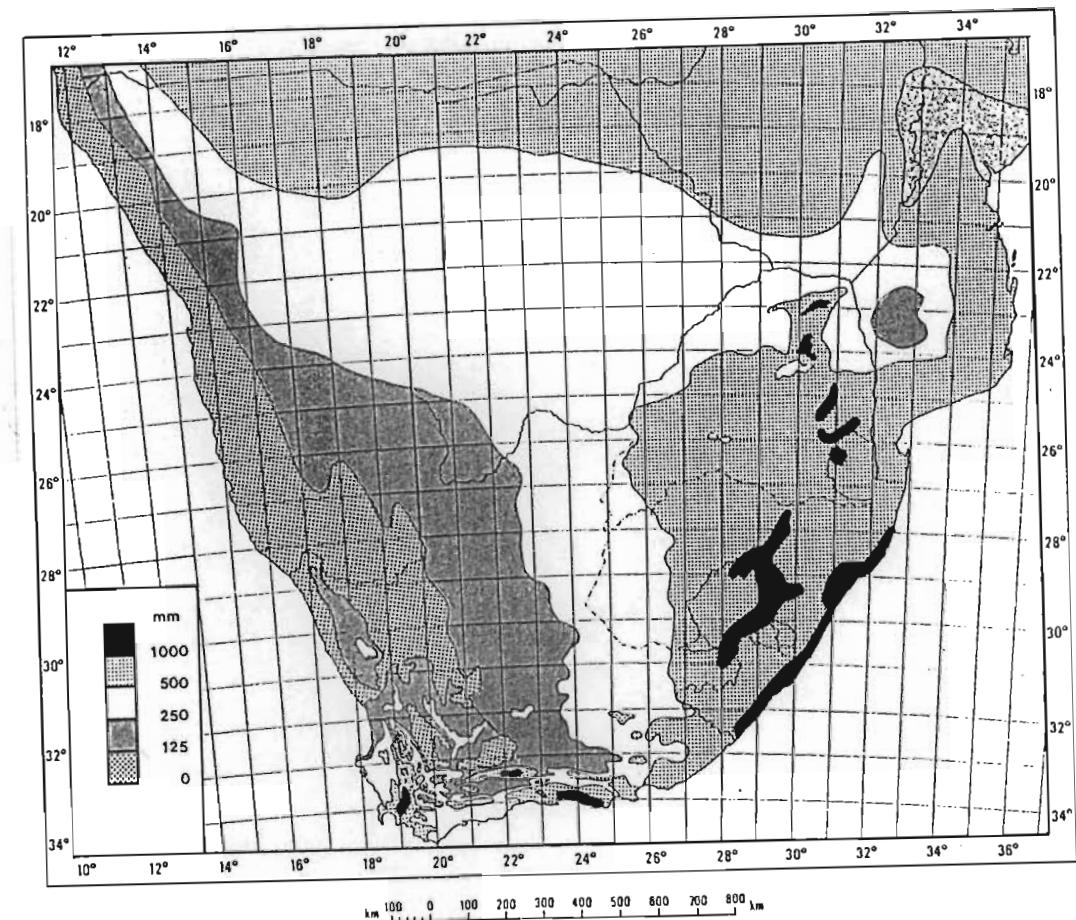

Figure 7. Recorded distribution of species with large stipules and map illustrating average rainfall in southern Africa (adapted from Schultze 1980 & Schutte 1988).

A. speciosum and its allies (*A. longifolium* and *A. baptisoides*) are glabrescent with annual aerial parts and dorsiventral, amphistomatous leaves. *A. filiforme* and its allies (*A. tuberosum*, *A. harveyanum*, *A. pseudotuberosum* and *A. angustissimum*) produce strongly dimorphic leaves which vary in morphology, anatomy and trichome distribution. The lower leaves are amphistomatous, sparsely hairy and dorsiventral. The upper leaves are hypostomatous, glabrous adaxially and tend towards isobilateral arrangement of the mesophyll.

3.1.5 Cytology

Goldblatt (1981) indicated that the cytology of *Argyrolobium* is inconsistent with its placement in the Genisteae. This situation was resolved by reclassification of the genus into the Crotalarieae (Van Wyk and Schutte 1989).

Table 4. *Argyrolobium* Chromosome numbers (2n) and source literature.

| | | |
|----------------------|----|---|
| <i>A. fischeri</i> | 32 | Frahm-Leliveld 1969 |
| <i>A. flaccidum</i> | 26 | Bir & Sidhu 1966 |
| <i>A. linnaeanum</i> | 48 | Lorenzo-Andreu 1951, Larsen 1956, Gilot 1965 |
| <i>A. tomentosum</i> | 30 | Larsen 1956, Gilot 1965 |
| <i>A. tomentosum</i> | 32 | Frahm-Leliveld 1969 |
| <i>A. variopile</i> | 30 | Van Wyk & Schutte 1988 |

Van Wyk and Schutte (1988) reported counts ($2n$) of 30 and 32 from *Polhillia* which shares a base number of 8 with *Argyrolobium*. Despite the paucity of counts available for *Argyrolobium* it appears highly variable.

3.1.6 Alkaloids

The pioneering alkaloid work of Van Wyk and Verdoorn often in association with others (1988, 1988a, 1988b, 1989, 1990) has been instrumental in realigning classifications of the South African Crotalarieae. This data compliments the work of Salatino & Gottlieb (1980, 1981) which was restrictive in its perspectives on the tribe. Van Wyk & Verdoorn (1990) provide a list of alkaloids reported from the Crotalarieae and a cladistic analysis based on their occurrence. In this synopsis *Melolobium*, *Dichilus*, *Polhillia* and *Argyrolobium* form a specialised group with alpha-pyridone alkaloids.

Ammodendrine, sparteine and luponine are common to much of the Crotalarieae but the remaining alkaloids present in *Argyrolobium* are more restricted. *Polhillia* shares all its alkaloids with *Argyrolobium* but is not as diverse, lacking $\Delta 5,6$ -luponine, argyrolobine and aphylline.

A preliminary survey of 12 *Argyrolobium* species (Van Wyk & Verdoorn 1989) lists the following alkaloids; anagyrine, cytisine, *N*-methylcytisine, luponine, sparteine, 5,6-dehydrolupanine, ammodendrine and aphylline. Conspicuous

differences in the relative proportions of anagyrine, cytisine, *N*-methylcytisine, lupanine and sparteine occur in the survey however the occurrence of these compounds is uniform and consolidates generic limits. In addition Tsuda and Marion (1964) reported the occurrence of argyrolobine which appears limited to *A. megarrhizum*.

3.2 SEXUAL CHARACTERS

3.2.1 Inflorescence Structure

Various acropetalous racemes characterise most legumes (Tucker 1987). They are based on an alternate pattern of bracts with axillary flowers. Edwards & Getliffe Norris (1990) and Van Wyk (1991) attached taxonomic significance to inflorescence structure and habit in *Buchenroedera* and *Lotononis*. Suffrutescent species with annual stems have inflorescences which terminate seasonal growth and shrubby perennial species have leaf-opposed inflorescences.

The Crotalarieae are also characterised by reductions in the number of flowers per inflorescence and shortening or lengthening of the rachis and pedicels. Sessile and subsessile flowers are sometimes important in classification i.e. *Lotononis* section *Synclistus* and *Aspalathus* subgen. *Ecklonella*. This trend of reduction is also reported from *Argyrolobium* and *Dichilus* (Van Wyk & Schutte 1989).

Bracts and bracteoles are widespread in the Crotalarieae and Van Wyk (1991) assigned taxonomic significance to the absence of bracteoles from *Lotononis* in

justifying his wide generic circumscription. Exceptions occur in sections *Listia*, *Lipozygis* and *Leptis*, with large bracts and loss of bracteoles considered apomorphic. Infrageneric bract variation also occurs in *Aspalathus* (Dahlgren 1968) where bract morphology characterises the subgen. *Triplobractea* and is important in the recognition of other groups.

A number of the Genisteae s.s. have bracts inserted above the pedicel base (Polhill 1976). Within the Crotalarieae various patterns have been reported but in most instances the bracts are inserted at the pedicel base. Species of *Lotononis* sections *Lipozygis* and *Leptis* have elevated bract insertion of taxonomic significance (Van Wyk 1989).

Inflorescence characters such as the absence of bracts and bracteoles and the occurrence of 'pseudopeduncles' (in which the vegetative node below the inflorescence is extended) serve as complementary evidence for the recognition of *Polhillia*.

The inflorescences of *Argyrolobium* complement habit data in delimiting a number of groups. In large suffrutescent species many-flowered racemes terminate the annual stems and mass flowering occurs. In groups with perennial stems inflorescences develop from apical meristems but become leaf-opposed due to subapical vegetative growth. Most species within this group produce fasciculate

inflorescences atop peduncles however *A. filiforme*, *A. harveyanum*, *A. petiolare*, *A. collinum*, *A. velutinum* and *A. candicans* produce sessile or subsessile leaf-opposed inflorescences. In all perennial-stemmed species trap-line foraging is likely due to the paucity of open flowers. In addition the group produces cleistogamous flowers often with reduced peduncles (Figure 1).

Bracts and bracteoles are prevalent in the genus and usually resemble each other. Distinctive, large and cymbiform bracts occur in *A. amplexicaule* and *A. crinitum* but the remaining species produce lanceolate to ovate bracts which are variously attached to the peduncles and pedicels. The anatomy of the pedicels was investigated for evidence of panicle reduction but none was found.

Bracteoles are common in the genus and are inserted either on the pedicel or calyx. These organs vary from ovate to setaceous and in *A. molle* they are often absent. The insertion of bracts and bracteoles is variable even on a single inflorescence and thus no taxonomic significance is attached to it.

3.2.2 Flowers

Floral structure within *Argyrolobium* is consistent and relatively unspecialized. Only two groups of species diverge from this pattern. In *A. amplexicaule* flowers are reduced in size and densely arranged, consequently the standard does not reflex fully and the flowers are somewhat elongate. In *A. speciosum* and its allies

the standard base is modified.

3.2.3 Calyx

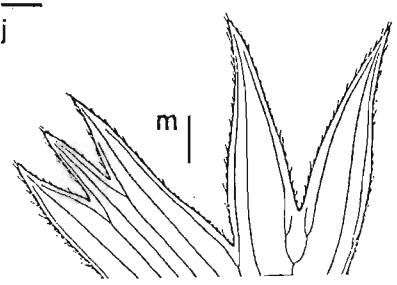

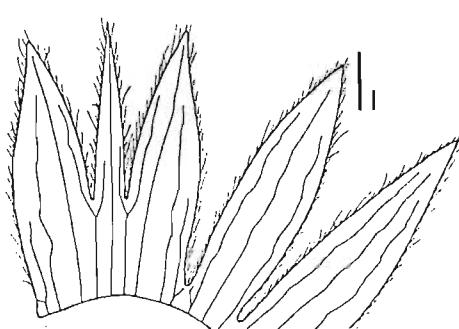

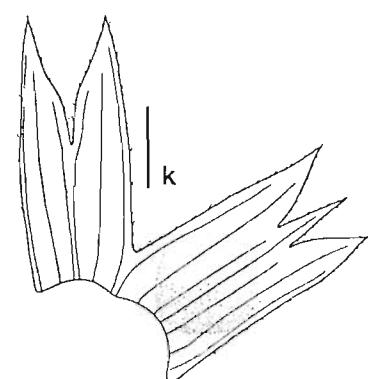

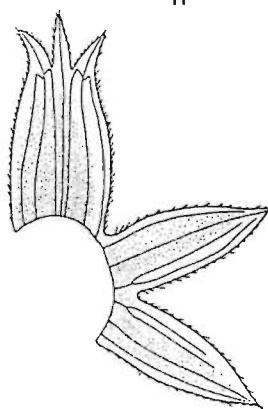

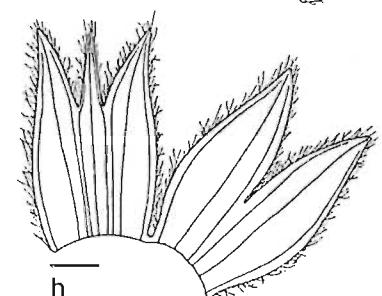

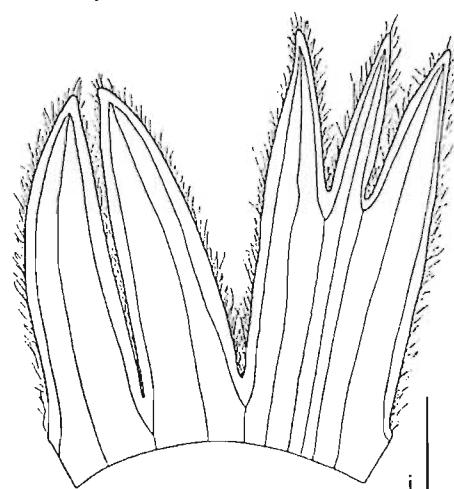

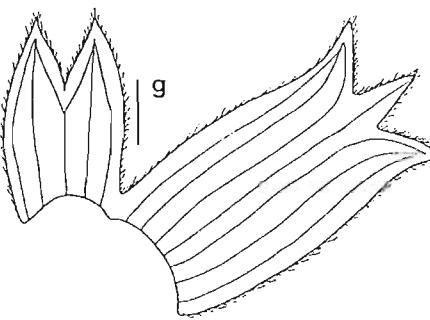

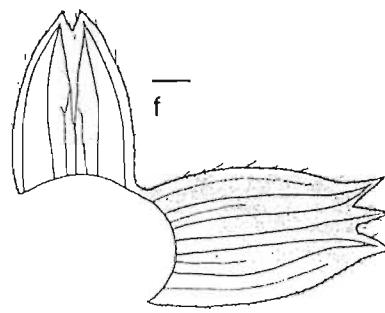

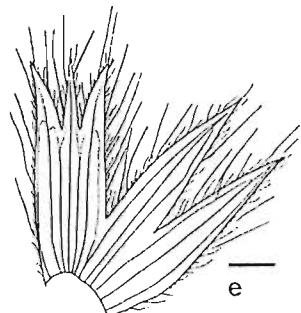

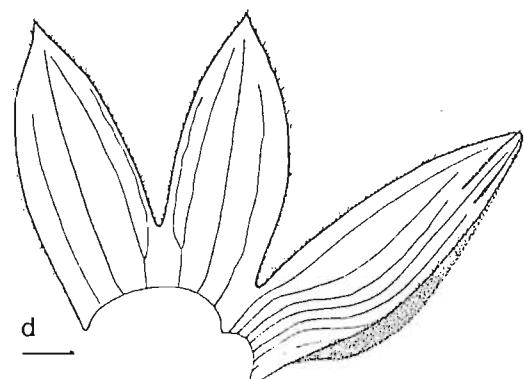

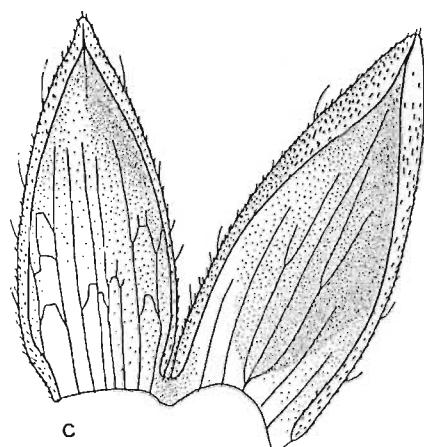

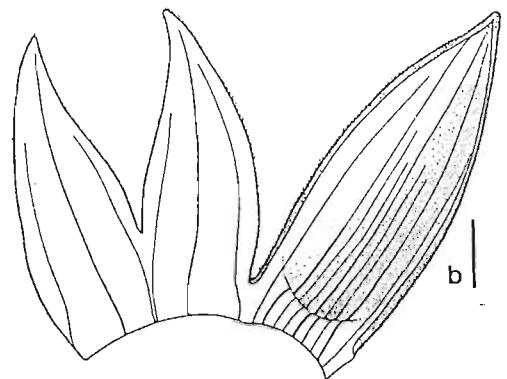

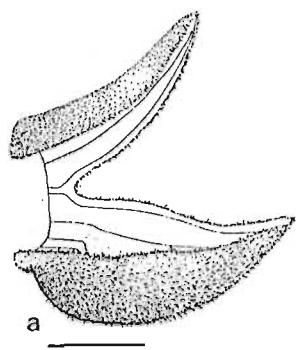

Variation of calycine morphology within the Papilioideae has been influential in classification. Within the Crotalarieae two groups are discernable on calyx structure. The first includes genera exhibiting a more or less pentamerous calyx such as *Aspalathus*, *Lebeckia* and *Lotononis*. The second group is characterised by genera with bilabiate calyces and includes *Anarthrophyllum*, *Melolobium*, *Dichilus*, *Polhillia*, and *Argyrolobium*. A convergent pattern occurs in the Genisteae in *Adenocarpus* (Genistinae), *Cytisus* (Genistinae), *Genista* (Genistinae), *Ulex* (Genistinae), and *Lupinus* (Lupininae).

7

The evolution of calyces is a compromise between protection of flowers and nectaries, support of landing platforms and erection of standard petals. In most species of *Argyrolobium* the upper sinus is very well developed however exceptions do occur (Figures 8, 9 & 10). In species with complex thickening at the standard bases, the upper calyx sinus tends to be shallower i.e. *A. longifolium*, *A. baptisioides*, *A. speciosum* and *A. pseudotuberous* (Figures 8 & 10). In addition the standard claws are elongate and perpendicular to the blade

Figure 8.

Bars = 2 mm.

(Figure 11) thus reducing constraints imposed by the calyx by displacing the point of standard erection. Section *Polyphyllum* also displays reduced upper sinus development (Figure 10). All these species produce large flowers *en masse* which reduces the importance of erect standards due to the composite visual impact of the inflorescence.

8

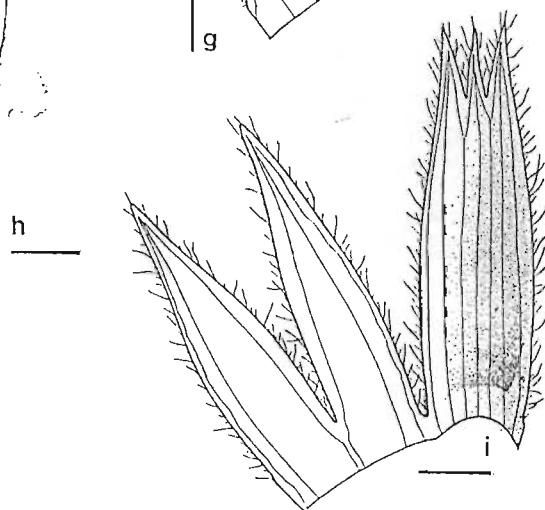

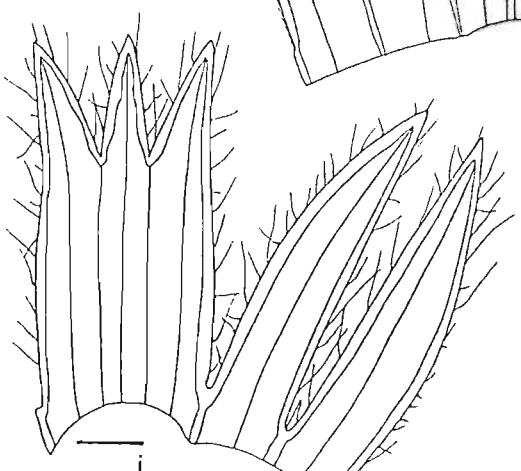

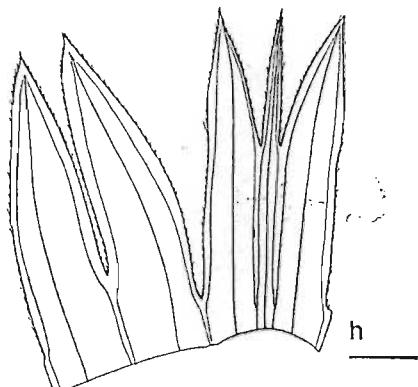

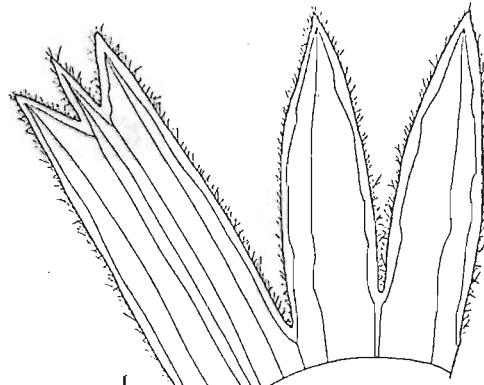

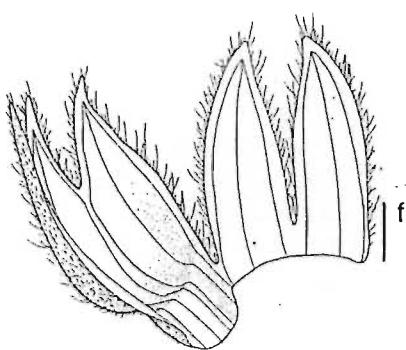

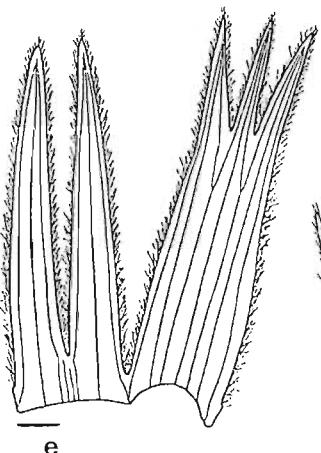

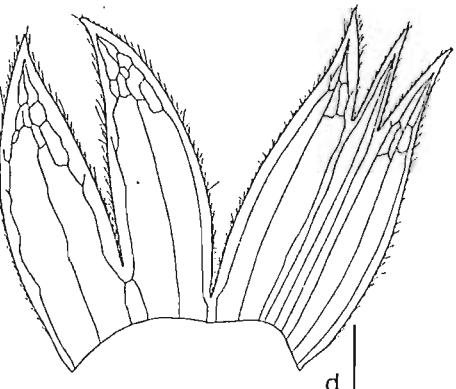

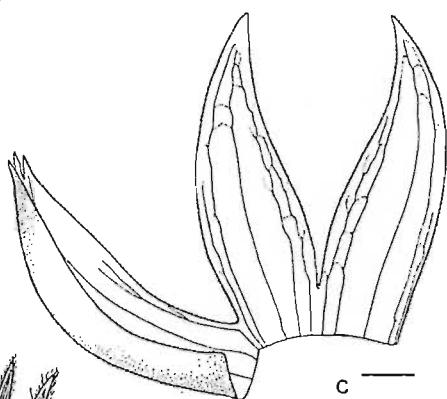

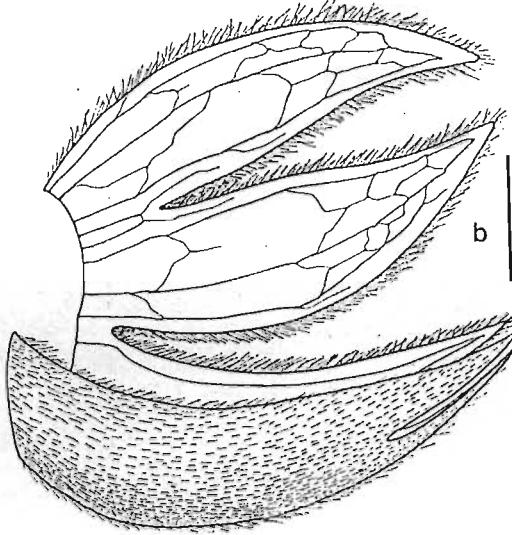

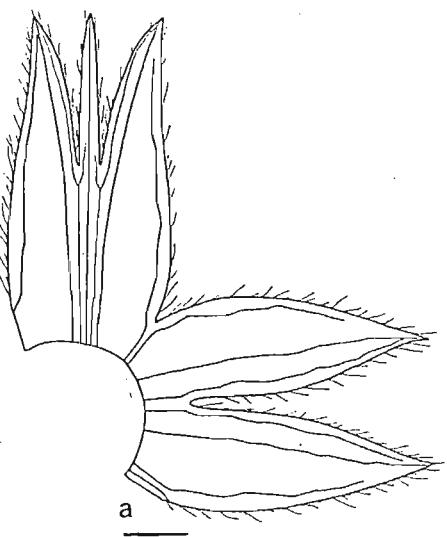

In section *Polyphyllum* the lobes of the lower lip are also reduced or vestigial and may provide added support to the landing platform.

3.2.4 The Corolla

In addition to visual orientational cues for pollinators 'Duftmale' patterns (areas secreting volatile oils) have been recorded in the Genistinae (Adey 1982). Our investigation included a survey of these patterns in *Argyrolobium* where fresh

Bars = 2 mm.

material was available. The results of this survey show a consistent pattern concentrated at the base of the standard petals of all species investigated. Wing petals occasionally showed a very diffuse pattern and keel petals revealed no pattern.⁹

The Standard

The standard petals of *Argyrolobium* are remarkably consistent (Figures 11 & 12) and are, for the most part, sub-orbicular with varying densities of trichomes on the adaxial surface. Claws are slightly thickened and seldom exceed 3 mm. In some instance the lamina base is ornamented (*A. pseudotuberosum*, *A. baptisioides* and *A. speciosum*) and canaliculate (*A. amplexicaule* and *A. baptisioides*). These modifications are apomorphic and enhance the basal strength of the petals.

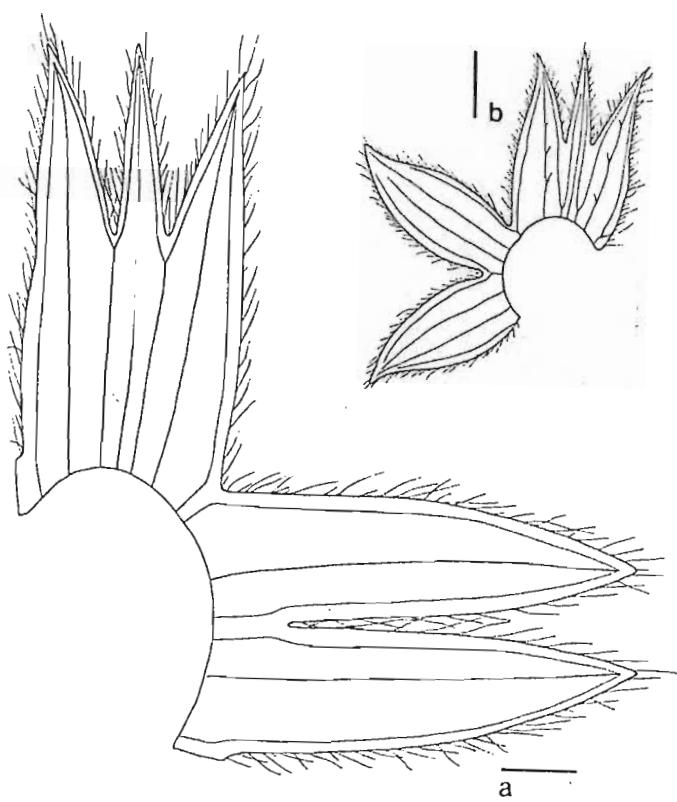

The Wings

Many papilionoid species possess rows of wrinkles, lunae, rugae or lamellae on the outer surfaces of the wing petals. The terminology of Stirton (1981) is

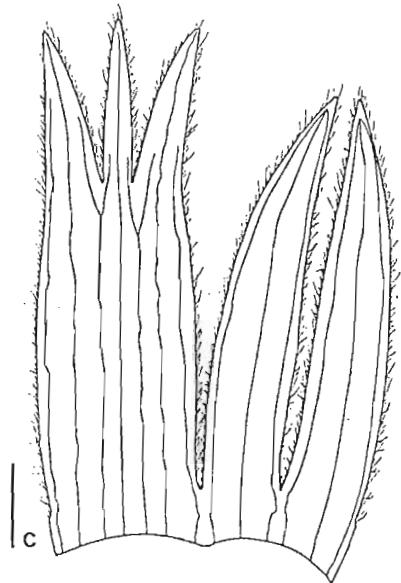

⁹

followed in describing the distribution and type of petal sculpturing. Petal sculpturing and appears to have evolved in conjunction with mellitophilous pollination syndromes (Arroyo 1981) and provides traction for pollinators (Tewari & Nair 1979; Stirton 1981 and Edwards 1984). Species-specific patterns have been reported in *Aspalathus* and *Wiborgia* (Dahlgren 1963 & 1975) and the Indian component of *Crotalaria* (Tewari & Nair 1979). However petal sculpturing is not usually species-specific (Stirton 1989; Edwards 1984 & 1987).

10

Wing micromorphology is also modified by the occurrence of trichomes which are sometimes of taxonomic value (Edwards 1987; Van Wyk 1991).

Figure 11.

Standard petals of *Argyrolobium*: a. *A. wilmsii*, abaxial view, b. lateral view (Edwards 562); c. *A. incanum*, abaxial view (Edwards 478); d. *A. pseudotuberousum*, lateral view, e. abaxial view (Edwards & Burrows 1015); f. *A. speciosum*, lateral view, g. abaxial view (Edwards 575); h. *A. longifolium*, lateral view, i. abaxial view (Edwards 402); j. *A. baptisioides*, abaxial view, k. lateral view (Edwards 434); l. *A. splendens*, oblique abaxial view (Krauss 927); m. *A. amplexicaule*, abaxial view (Edwards 336); n. *A. crinitum*, oblique abaxial view (Drège s.n.); o. *A. lunare*, abaxial view (Williams 757). Bars = 2 mm.

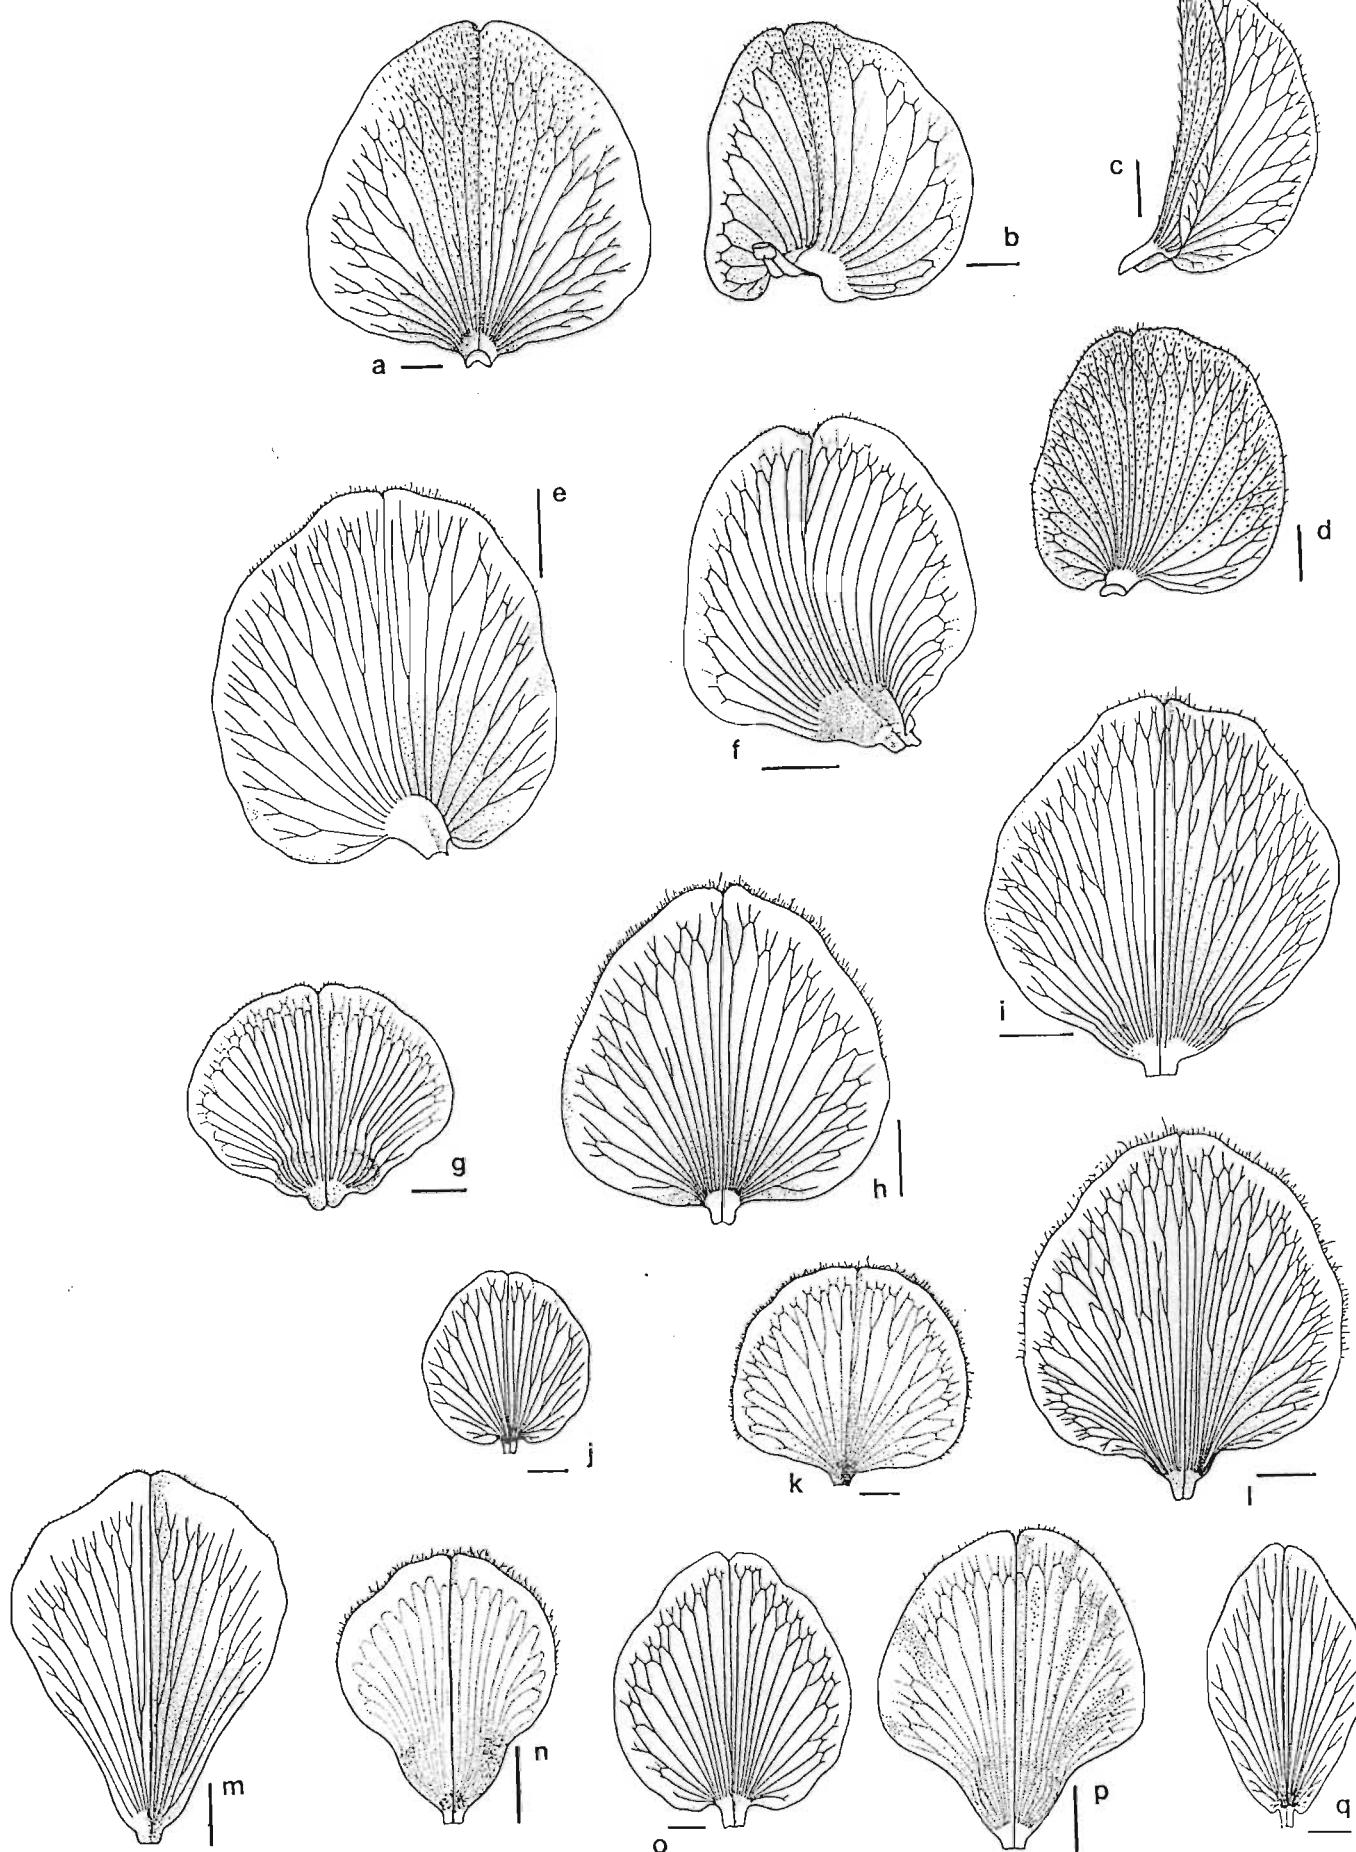

The wing petals are generally longer and narrower than the keel petals in *Argyrolobium*. Most species display petal sculpturing of varied distribution across the outer surface. The most common zones of ornamentation in *Argyrolobium* are the upper basal and the upper central zones (Figure 13) however patterns are intraspecifically variable. Sculpturing is always transcostal and of the lunate-lamellate type (Figures 15, 16, 17). The loss of sculpturing has occurred independently in many of the sections (Figure 14) and is considered apomorphic.

Wing vestiture occurs intermittently in several species and does not correlate to sectional characters.¹¹

The Keel

The keel petals of *Argyrolobium* are always valvate and shorter than the wing petals. They are fused along their lower margin and have blunt apices which represents an unspecialised condition within the tribe. The use of keel vestiture in

the delimitation of taxa is possible in sections of *Lotononis* (Edwards 1987; Van Wyk 1991) however within *Argyrolobium* this character is unstable. In other aspects keel morphology is consistent throughout the genus (Figures 15, 16, 17).

3.2.5 The Androecium & Palynology

A progressive fusion of filaments occurs within the Podalyrieae and Crotalarieae. Associated with this trend is an increase in anther dimorphism. Bentham (1865) placed strong emphasis on these sexual modifications in the generation of classifications but with the accumulation of systematic data it has become increasingly apparent that these trends are often convergent (Polhill 1976; Van Wyk & Schutte 1989). The complete fusion of the staminal sheath in *Argyrolobium* was the primary character used to justify its placement within the Genisteae s.s.

Staminal dimorphism occurs in *Argyrolobium* with five short stamens with large basifixed anthers and five long stamens with small dorsifixed anthers. Occasionally hairs occur on the thecae of *A. lunare*.

Filament fusion occurs late in floral development and is variable within *Argyrolobium*. Strong trends towards diadelphy are present in *A. harveyanum*, *A. lunare* and *A. sericosemium* (for which the term pseudodiadelphy is used) but monodelphy with adaxial cleavage is more common. Complete adaxial cleavage occurs only in *A. baptisioides*, *A. pseudotuberosum*, *A. speciosum*, *A. tuberosum* and *A. longifolium* and appears to be a reversal.

Palynology has provided many characters for delimiting natural groups in plant

phylogeny (Walker & Doyle 1976 & Blackmore 1984). Pollen variation within the Crotalarieae is however comparatively small and concerned mainly with aperture structure but Ferguson & Skvarla (1981) consider it useful in tribal circumscription. The Podalyrieae and Genisteae s.l. are distinguished by the raised surface reticulation (supra reticulation) of their pollen grains (Polhill 1976).

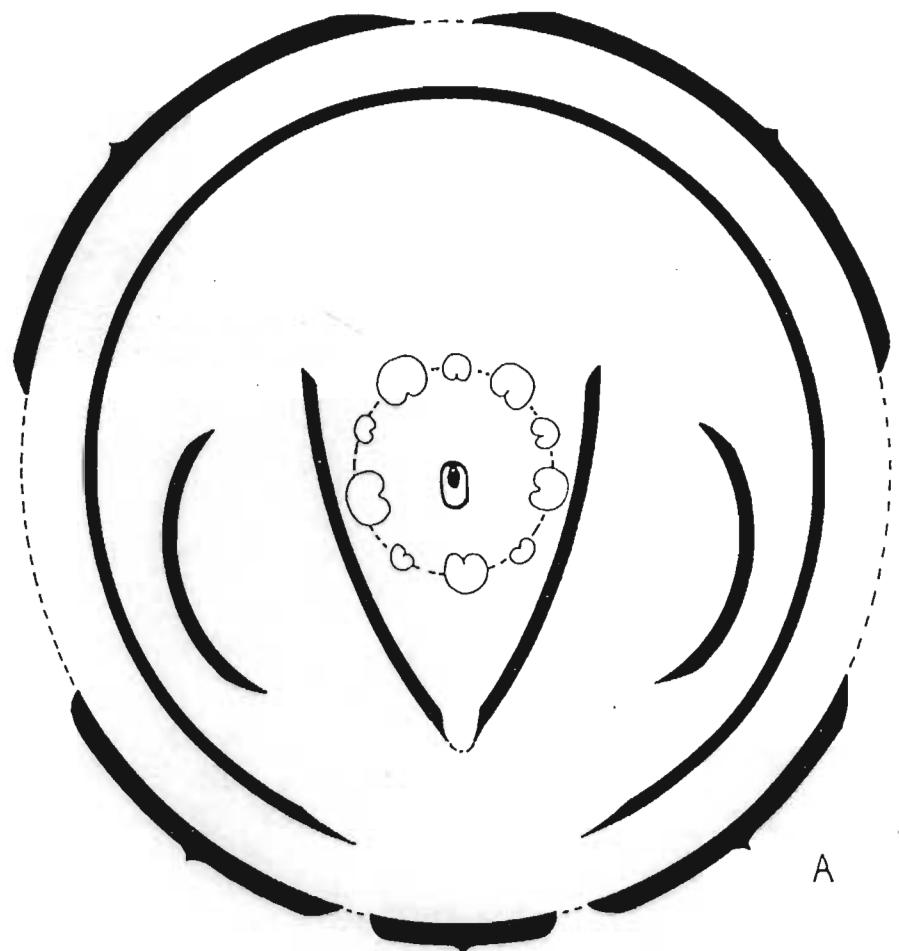

Tricolporate pollen is prominent in the Crotalarieae while tricolporate grains occur in the Liparieae, Podalyrieae and Sophoreae. Consequently the former pollen type is regarded as specialised (Ferguson & Skvarla 1981; Guinet 1981). Within the Crotalarieae tricolporate pollen is common to *Aspalathus*, *Bolusia*, *Melolobium*, *Dichilus* and *Argyrolobium*. *Wiborgia* and *Lebeckia* have tricolporate grains with small apertures in the endexine.

Argyrolobium is stenopalynous and grains are prolate, tricolporate and apocolporate throughout (Figure 18). Grain size ranges, 18–25 x 15–18 μm , and surface micromorphology is consistently reticulate with slight variation in pattern definition.

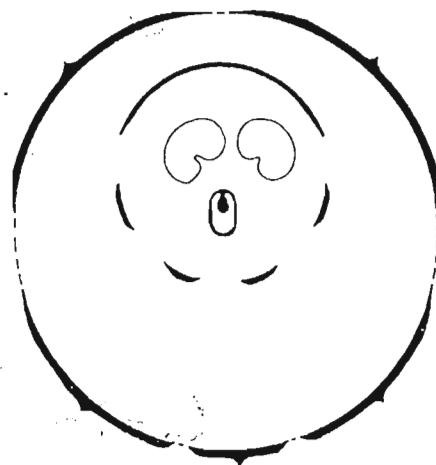

Sections through the grain wall reveal relatively unspecialised stratification which conforms with the patterns reported by Ferguson & Skvarla (1981) (Figure 18).

3.2.6 Breeding systems

The phenomenon of cleistogamy is common in the flowering plants and involves

A

B

Figure 19.

Floral diagrams of *Argyrolobium*. A. Chasmogamous flower; B. cleistogamous flower.

the sexual production of seed without anthesis. In some instances this is combined with reductions in the number and size of floral organs leading to floral dimorphism. Within the Crotalarieae most cleistogamous species show little floral modification and dimorphism has only been reported from *Argyrolobium* (Harms 1909, 1917; Polhill 1968; Edwards, van Staden & Stirton 1992) and *Lotononis* (Van Wyk 1990). Comparisons of the degree of floral dimorphism displayed by these genera reveals that reduction is extreme in *Argyrolobium* (Figure 19) and fairly minor in *Lotononis*.

To understand the uniform pattern of organ abortion in cleistogamous flowers of *Argyrolobium* its floral development was investigated. Within the Papilioideae floral development follows a pattern which is unusual in the angiosperms (Tucker 1984). Zygomorphy of the corolla is established with the asymmetrical initiation of the petals. Standard primordia develop first followed by the wings and then the keel (Figure 20). This dorso-ventral pattern is repeated in the stamens which, although monodelphous in chasmogamous flowers, are initiated as two separate whorls (Figure 20). The outer whorl comprises 5 large anthers on short filaments which develop before the inner whorl of 5 small anthers on long filaments. Development is initiated in the adaxial organs of each successive whorl, and progresses abaxially. In addition the development of the whorls progresses centripetally but overlaps slightly thus the adaxial anthers of the outer whorl develop before the abaxial petals.

Figure 20. Floral development of *Argyrolobium molle*. A. Young cleistogamous flower showing the marked asymmetry of the petals and androecium; B. young chasmogamous flower showing the slightly asymmetrical development of the petals and large basifixed anthers; C. young cleistogamous flower with the calyx and carpel removed, note the absence of the five inner staminal primordia; D. young chasmogamous flower with the calyx and carpel removed, showing the inner staminal primordia; E. asymmetrical development of the calyx; F. adaxial view of the functional stamens and recurved style in a cleistogamous flower; G. lateral view of a young chasmogamous flower with the calyx removed showing the relative rates of organ development; H. lateral view of a mature cleistogamous flower with the calyx removed, note the unusual occurrence of anthers on the lower stamens (bars A, B, C, D = 110 μm ; E = 100 μm ; F = 1.9 mm; G = 200 μm ; H = 0.9 mm).

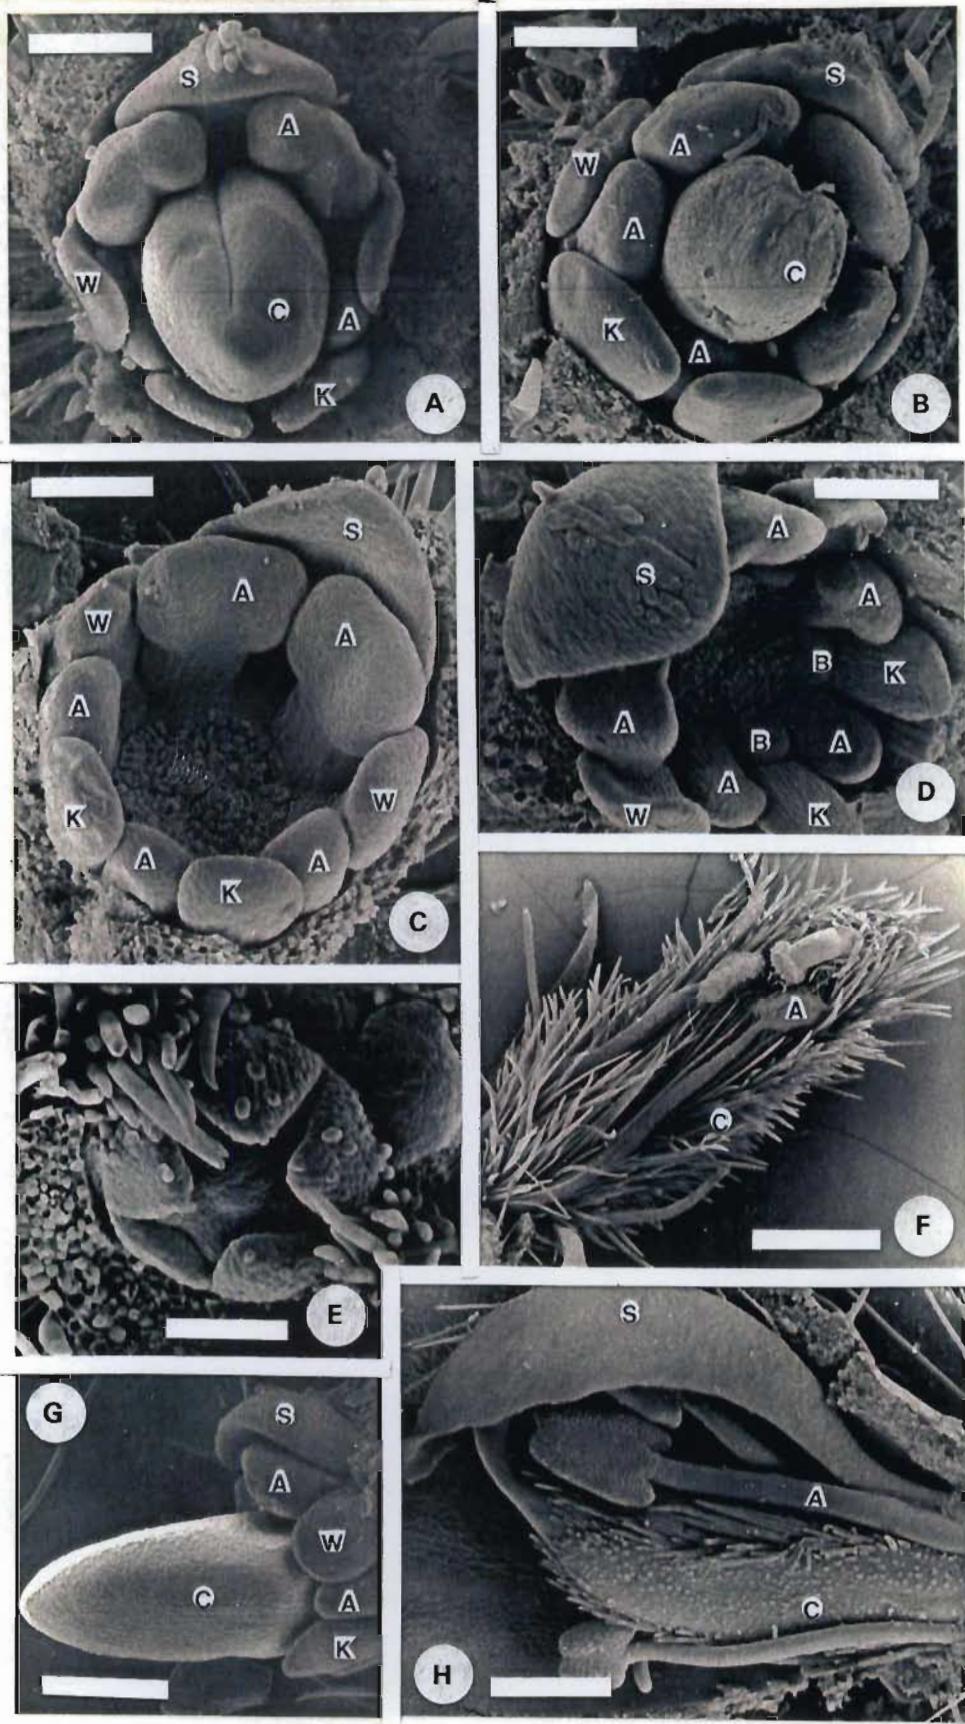

Fig 20.

Cleistogamous flowers of *Argyrolobium* display the loss or inhibition of several organs. The extent of inhibition is related to the position of floral primordia. Thus in cleistogamous flowers (Figure 21 & 22) the standard, although reduced, is always present, the wings usually occur as fragile spathulate appendages and the keel petals are filamentous. The androecium shows even greater reduction with only 2 functional anthers remaining. These correspond to the large abaxial anthers of the outer whorl. The remaining three stamens of this whorl usually occur as irregular filaments. On rare occasions the lateral stamens bear vestigial anthers but these seldom contain pollen and never achieve pollination due to their lateral placement. Stamens of the inner whorl are always absent. This reduction in stamens correlates to a major reduction in the amounts of pollen produced per flower. In addition, pollen loads of the retained anthers are reduced.

Cleistogamous styles are shortened and sharply recurved, making contact with the viable anthers. Pollen germinates *in situ* and grows through the anther walls into the stigma.

In chasmogamous flowers outbreeding is encouraged by separation of the sexual whorls through differential elongation of the filaments and styles. Pollen is deposited on the stigma through perianth distortion by visiting insects. In cleistogamous flowers this spacial separation is circumvented by abbreviation of the staminal filaments and style in conjunction with reflexion of the latter. The scenario conforms to progenesis (Lloyd 1983) in which specializations that reduce

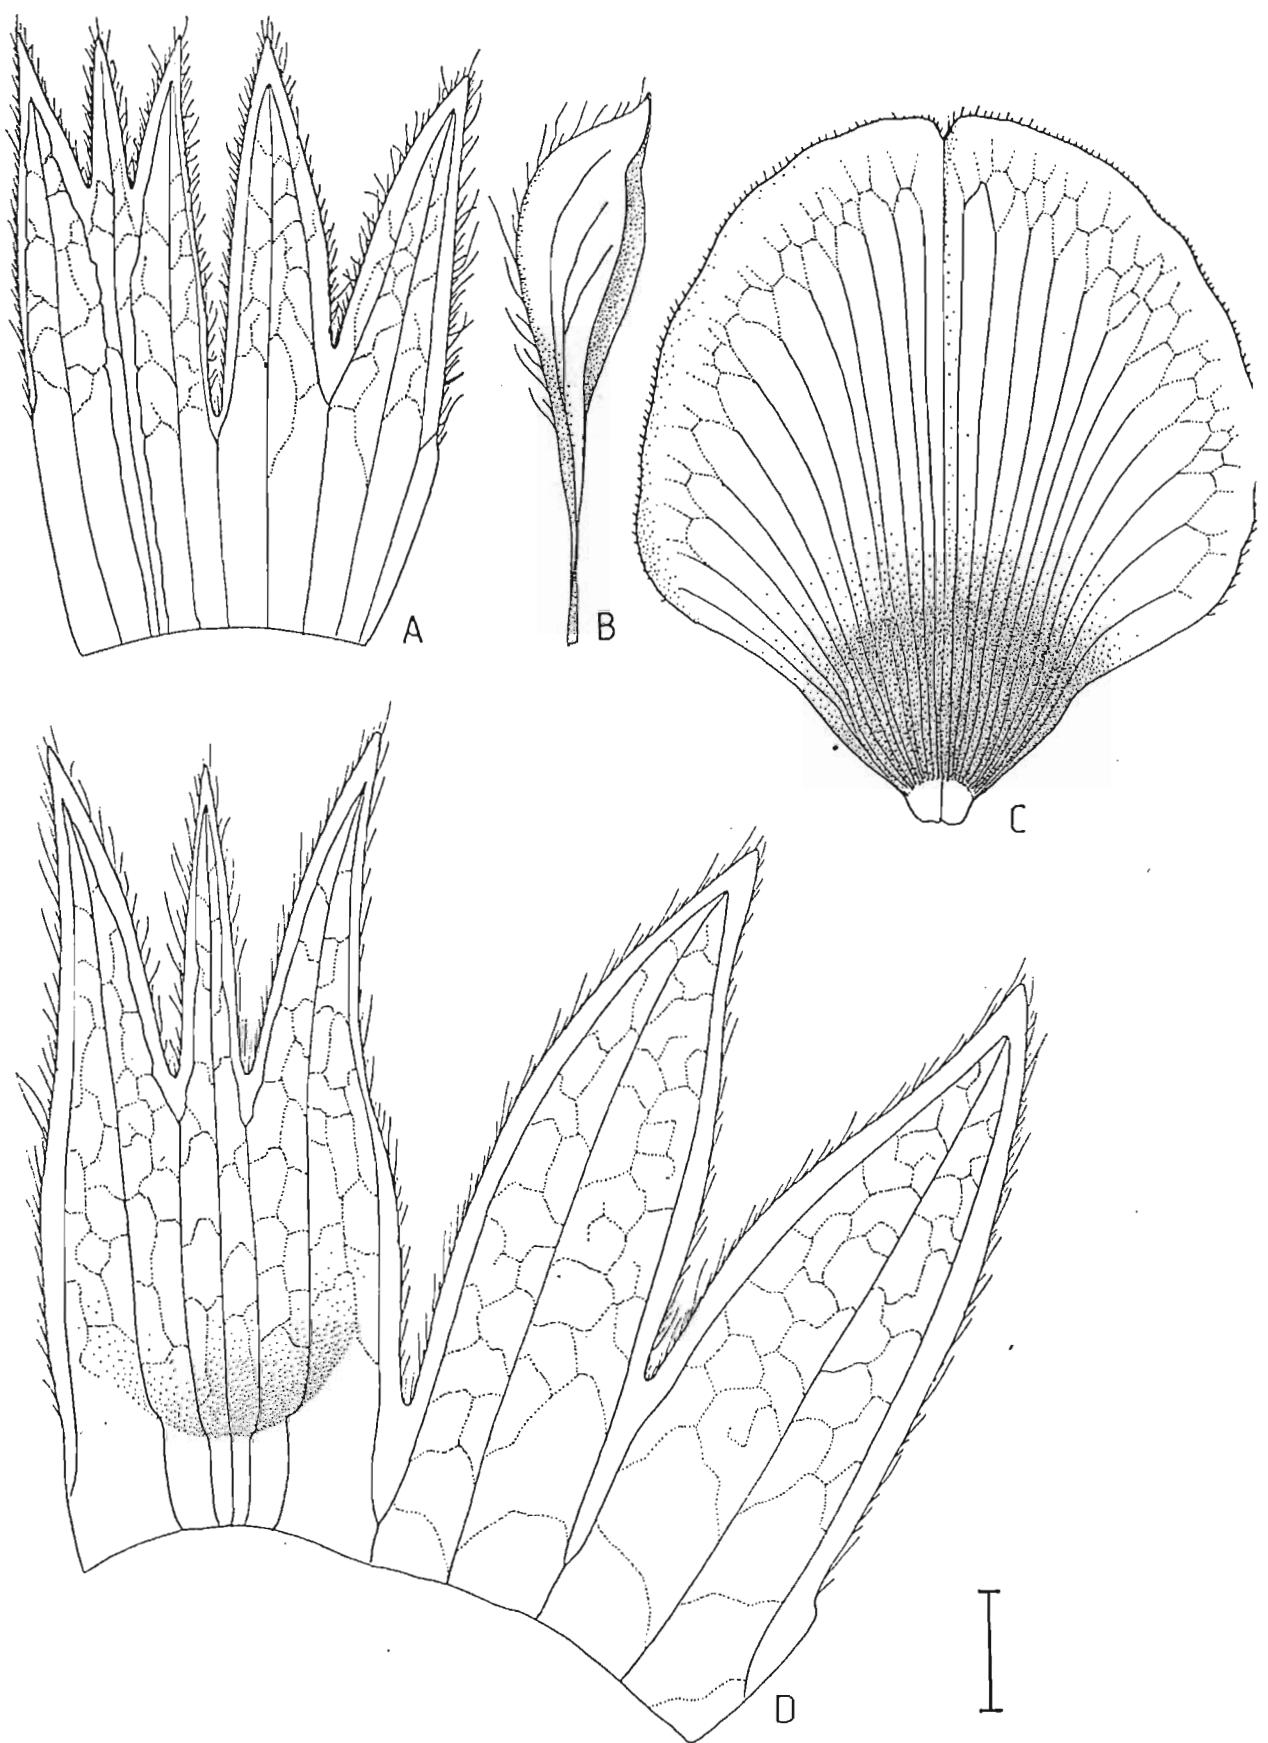

Figure 21.

Argyrolobium ascendens. A. Cleistogamous calyx; B. cleistogamous standard; C. chasmogamous standard; D. chasmogamous calyx. Bar = 3 mm. Voucher: Edwards

autogamy in chasmogamous flowers are overcome by the precocial maturation of sexual organs. It is significant that chasmogamous flowers of dimorphic species are more strongly outcrossing than monomorphic species. In dimorphic *Argyrolobium* species chasmogamous flowers are produced in low numbers, forcing pollinators to move between plants. This contrasts with monomorphic species which flower *en masse* thus enhancing geitonogamy.

Evolutionary consideration of the phenomenon requires a comparison of the success of the two flower types. Without pollinators chasmogamous flowers set little seed and cleistogamy overcomes this constraint. The genetic advantage of outbreeding is maintained by producing chasmogamous flowers when pollinators are available. This necessitates the perception of environmental stimuli by the plant resulting in seasonal production of different flower types. The cryptic nature of cleistogamous flowers reduces their vulnerability to pollen thieves and fruit predators. In addition, from field observations, it appears that cleistogamous production of seed early and late in the season is out of synchrony with larval stages of bruchid beetles as this seed is seldom parasitised.

Reduced paternal investment in cleistogamous flowers allows reproduction when resources are low (Schoen & Lloyd 1984). This capacity allows neoteny in dimorphic species of *Argyrolobium* which may behave as facultative annuals. Seed of *A. molle* (Edwards 486), *A. collinum* (Edwards 476), *A. rotundifolium*, *A. pumilum* (Edwards 480), *A. ascendens* (Edwards 506) and *A. stipulaceum*

(Edwards 459) was germinated and monitored for flowering. Most of these species commence flowering from between two and five months after germination and initial flowers were always cleistogamous.

Seed production in such instances is probably too low for the assumption of an annual existence over any lengthy period. However the strategy occurs widely in species of *Argyrolobium* and *Lotononis* from areas of the eastern Cape with unpredictable climate. Distributional data indicates that florally monomorphic species are limited to areas of predictable climate and that dimorphic species of *Argyrolobium* are widespread (Figure 23). Predictably these data also relate to habit. Dimorphic species are usually weakly perennial geophytes with diffuse flowering periods. By contrast, monomorphic species are large shrubby perennials or robust suffrutices with annual aerial stems. In these species growth is geared towards mass flowering and individuals require a number of years to reach reproductive status. Their distribution is somewhat curtailed (Figure 24).

In southern Africa *Argyrolobium* is limited to the eastern areas. Its absence from dry regions of the west coast, where rainfall is low and highly unpredictable, is attributed to the lack of annuals within the genus. This contrasts with *Lotononis* where annuals occur in the drier western regions (Van Wyk 1990). In both genera floral dimorphism is a seasonal alternative to outbreeding rather than a step towards autogamy. This explains the advanced state of dimorphism and the lack of annuals within *Argyrolobium* when compared with *Lotononis*.

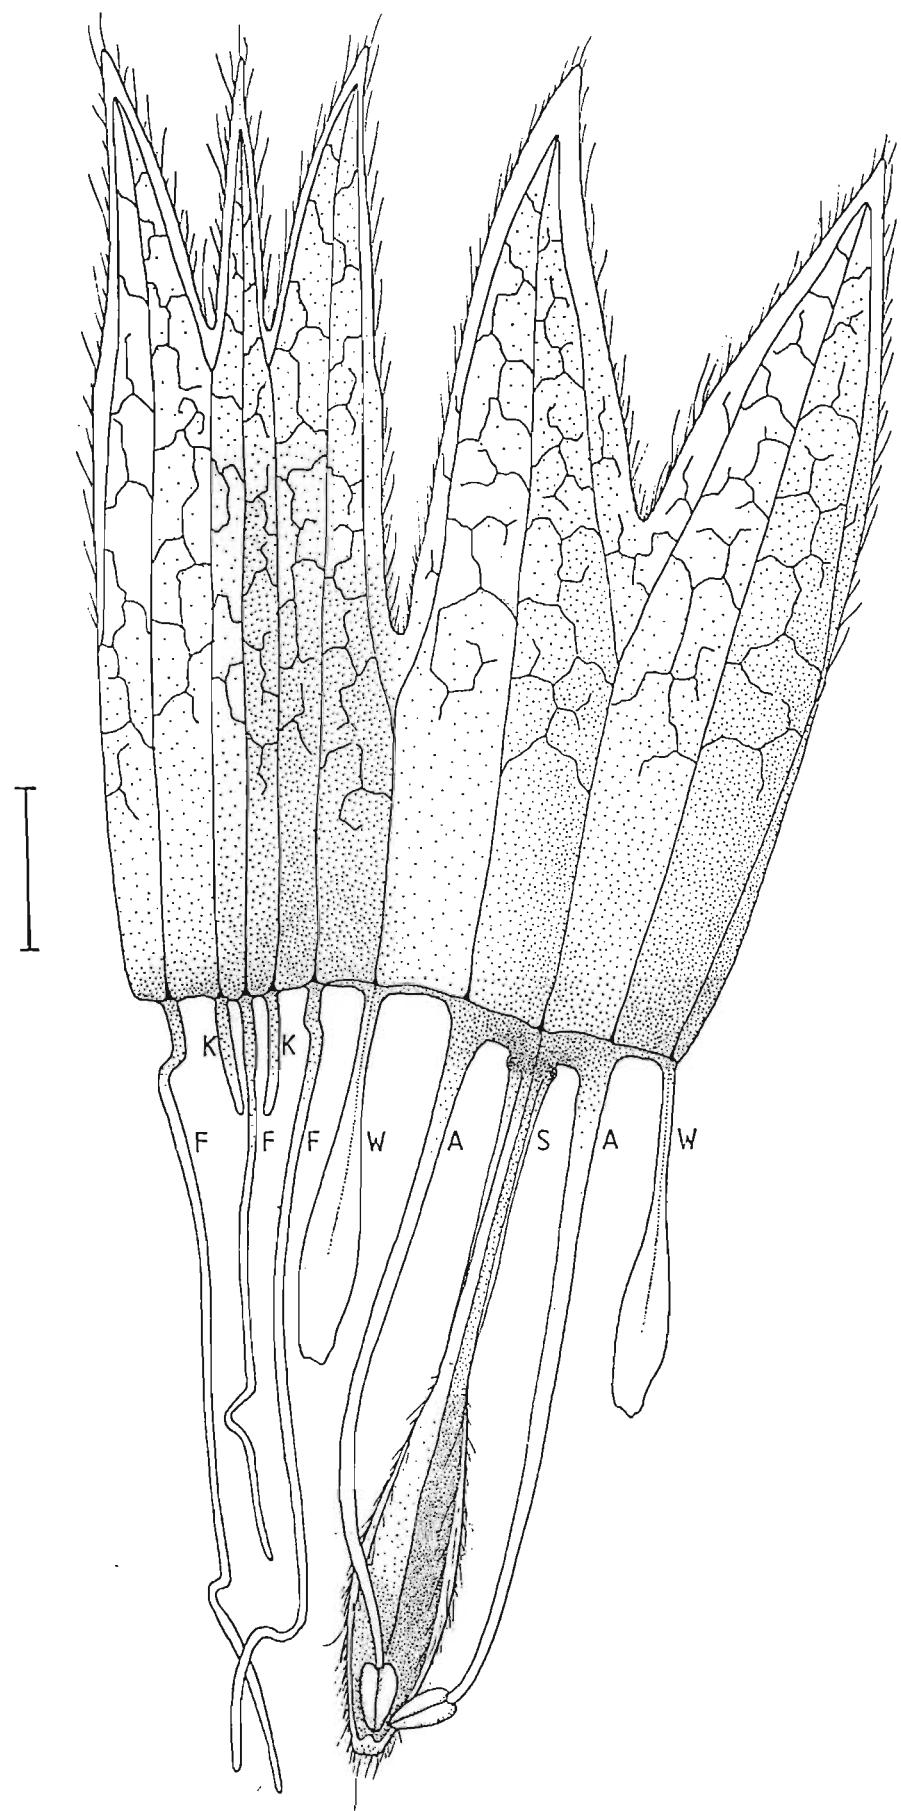

Figure 22.

Argyrolobium ascendens dissected cleistogamous flower with the androecium and corolla reflexed (A = fertile stamens, F = staminal filaments, K = keel petals, W = wings).

Previous reports (Harms 1909 & 1917) of floral dimorphism within *Argyrolobium* list 7 South African species. The current examination reveals 23 dimorphic species in South Africa.

Florally monomorphic species of *Argyrolobium* in South Africa: *A. amplexicaule*, *A. baptisioides*, *A. crassifolium*, *A. filiforme*, *A. frutescens*, *A. harmsianum*, *A. incanum*, *A. longifolium*, *A. lunare*, *A. megarrhizum*, *A. muddii*, *A. pachyphyllum*, *A. parviflorum*, *A. petiolare*, *A. polyphyllum*, *A. speciosum*, *A. transvaalense*, *A. trifoliatum*, *A. wilmsii*.

Argyrolobium species with dimorphic flowers in South Africa: *A. ascendens*, *A. argenteum*, *A. barbatum*, *A. campicola*, *A. candicans*, *A. collinum*, *A. filiforme*, *A. harveyanum*, *A. humile*, *A. lotoides*, *A. marginatum*, *A. molle*, *A. pachyphyllum*, *A. pauciflorum*, *A. pseudotuberousum*, *A. pumilum*, *A. rotundifolium*, *A. rupestre*, *A. sericozemium*, *A. stipulaceum*, *A. tomentosum*, *A. tuberosum*, *A. velutinum*.

The advantages conferred upon dimorphic species include the maximisation of seed set through assured pollination, reduced pollen and seed predation, an increase in the duration of the flowering season and precocial flowering. The disadvantage of reduced gene flow is minimised by the strongly outbreeding chasmogamous flowers.

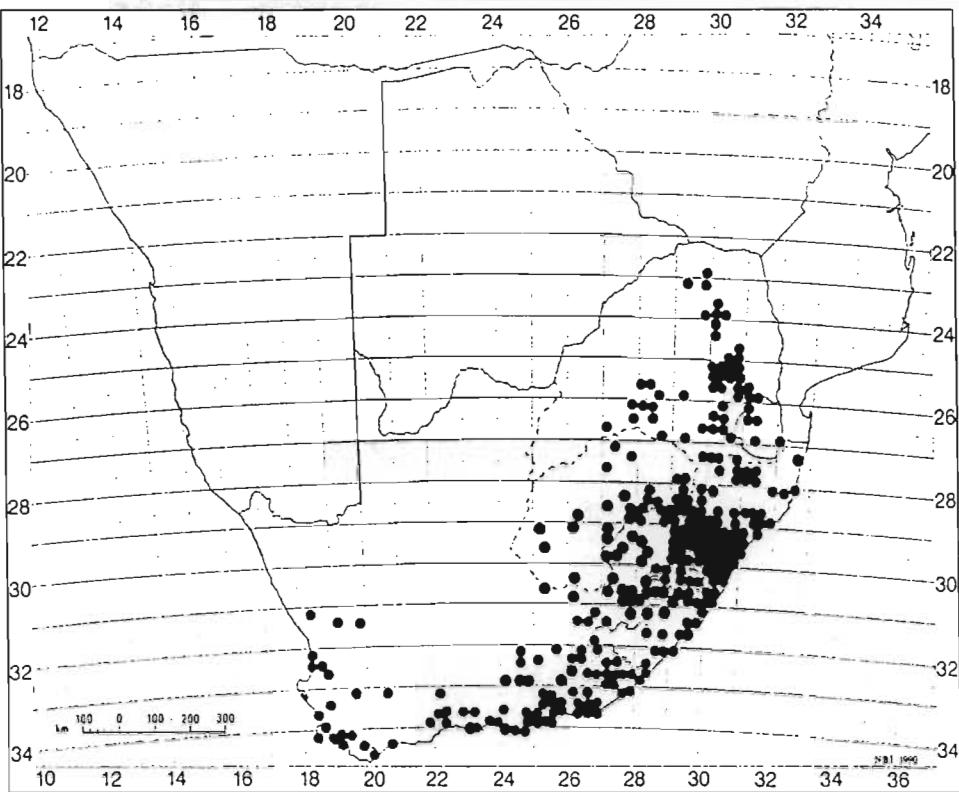

Figure 23.

Distribution of florally dimorphic species in South Africa.

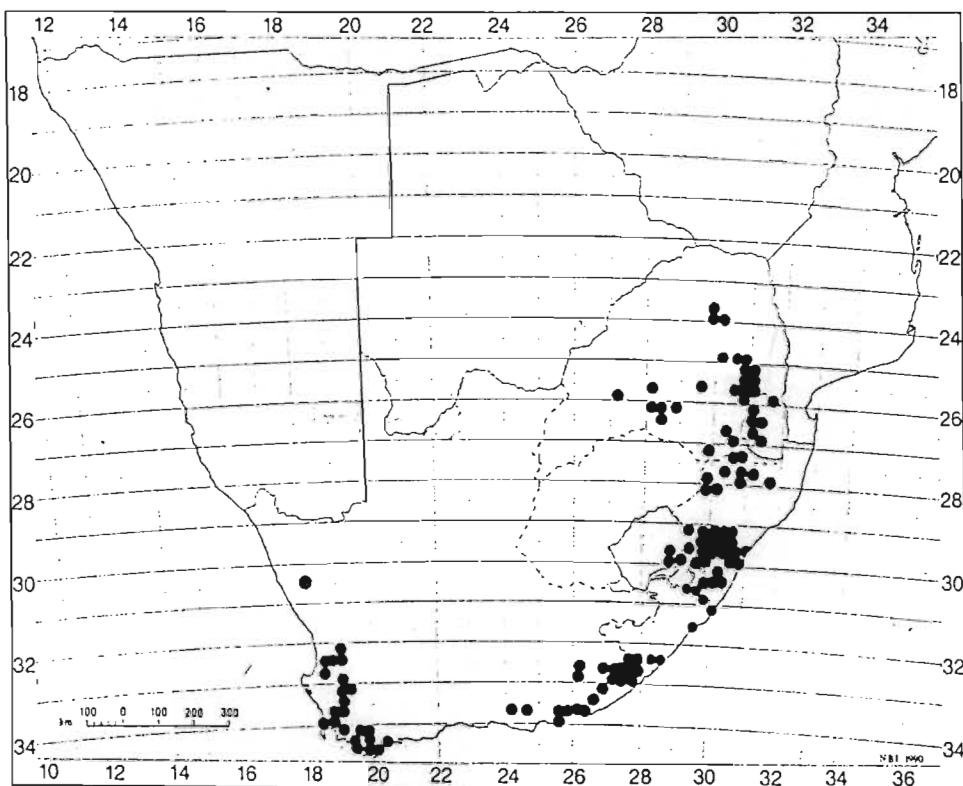

Figure 24.

Distribution of florally monomorphic species in South Africa.

3.2.7 Flowering Times

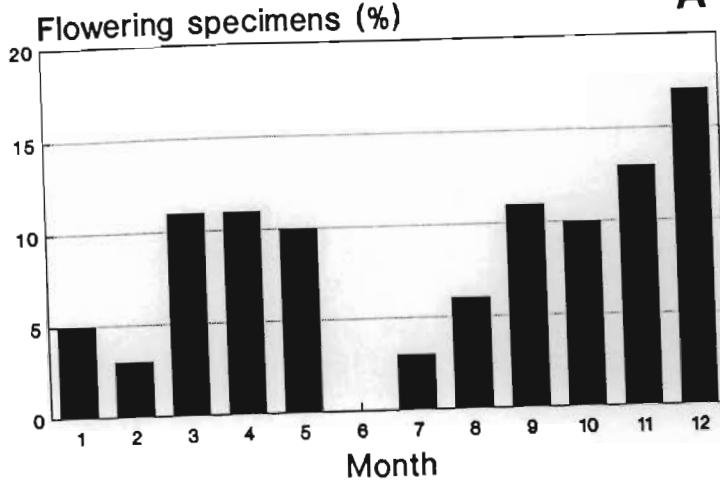

The flowering times for species included in this dissertation were obtained from herbarium specimens. Because such collections are made predominantly from chasmogamous specimens it was not possible to assess cleistogamous flowering in this way. Cultivated specimens of dimorphic species produce cleistogamous early and late in the season. Chasmogamous flowering times are presented as percentages of herbarium specimens collected in particular months (Figures 25, 26, 27, 28, 29, 30, 31). This data is biased by inconsistencies in the areas collected, the intensity of collecting across seasons and sample sizes for each species. Despite these flaws the data provides patterns worthy of interpretation.

Species from exceedingly dry habitats tend to flower opportunistically and consequently show rather erratic profiles (*A. argenteum* and *A. petiolare*). This behaviour extends into widespread species which traverse areas of different rainfall patterns (*A. molle*, *A. collinum*, *A. tomentosum*, *A. rupestre*, *A. rotundifolium*, *A. harveyanum* and *A. amplexicaule*). The trend is also apparent in eastern Cape endemics which have evolved diffuse and irregular flowering periods in response to the non-seasonal precipitation (*A. polyphyllum*, *A. trifoliatum*, *A. parviflorum*, *A. incanum* and *A. barbatum*). However the overwhelming chasmogamous pattern within the genus is summer flowering from October to February with very little flowering from April to August.

The chasmogamous pattern is augmented by cleistogamous flowering. Although

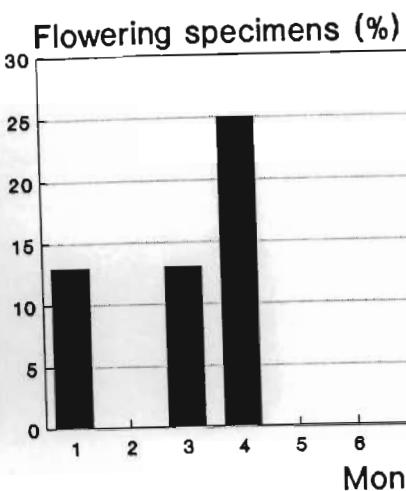

some degree of overlap between these flower types occurs cleistogamous flowers significantly extend flowering period into the early and late season. Of particular interest is the reduced incidence of cleistogamy in macchia vegetation. This transition is most marked in *A. filiforme* which seldom produces cleistogamous flowers compared to its close ally *A. harveyanum*. The two sections which appear to have evolved in fynbos vegetation (*Polyphyllum* and *Lunare*) do not display cleistogamy and its absence may represent a reversal. Certainly the opportunities for allogamy in herbaceous pyrophytes are limited in this vegetation and may favour chasmogamy and facultative outbreeding after fires. Presumably cleistogamous specimens are frequently overlooked by collectors.

CHAPTER 4

PHYTOGEOGRAPHY

If one accepts that the distribution patterns of biota are the product of their biology and the history of the environments in which they occur then the phylogeny of groups can be partly elucidated by their present distributions. Southern Africa is a mosaic of climatic zones, from strongly seasonal winter rainfall in the south to strongly seasonal summer rainfall in the east. Between these extremes there exists a continuum in which rainfall is not strongly seasonal. Superimposed upon climatic diversity are edaphic and topographic features which reach their height of expression in the Cape.

Bond & Goldblatt (1984) estimate that approximately 8578 species or 46% of the plant diversity in southern Africa falls within the Cape Floral Kingdom. Through geological time there has been considerable exchange of taxa between this southern vegetation and its northern neighbours resulting in the mélange of today.

- The vegetation patterns of southern Africa described by Acocks (1975), Oliver *et al.* (1983) & Weimarck (1941) have been useful in the present synthesis. Where possible these have been augmented by patterns reported in recent revisions of plant taxa.

Distribution patterns were generated from the cited herbarium specimens. Maps were plotted according to the grid reference system of Edwards & Leistner

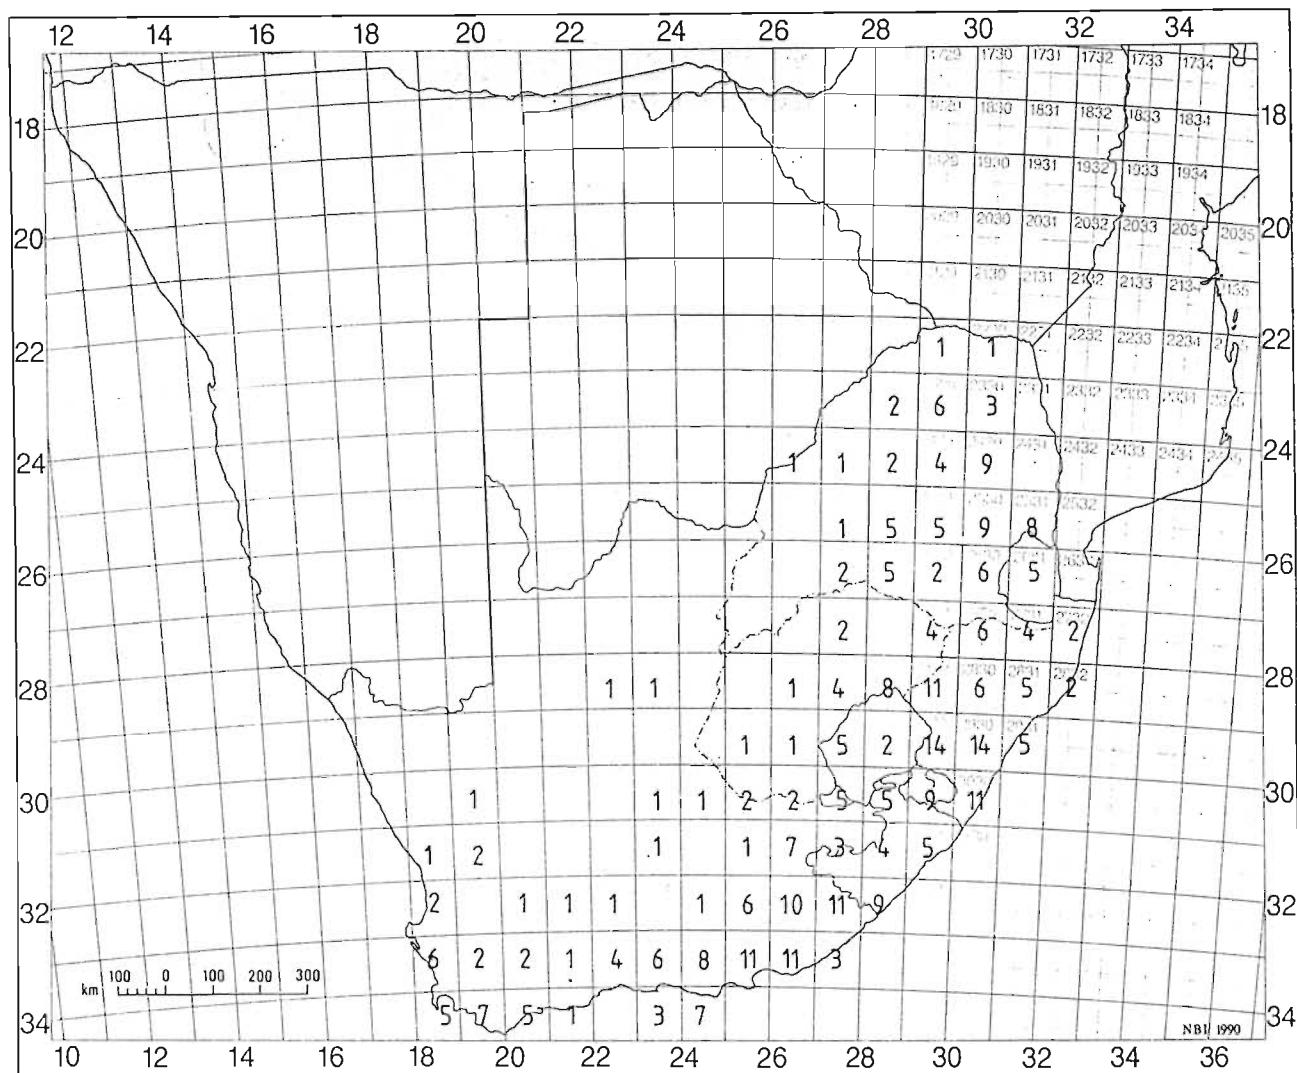

Figure 32. Species density recorded for *Argyrolobium*.

(1971). Individual records are plotted on $\frac{1}{16}$ divisions of $\frac{1}{16}$ squares. Maps indicating the concentration of species across South Africa, for the sections and for the genus, are provided in this chapter. The accuracy of these maps is limited by variation in collecting activity across the area under study and spurious collection data which has been disregarded when discernable. The coarse nature of the mapping system used, negates species density in some areas. This is prominent where geological or geomorphologic features occupy small portions of the plotting squares but support large species complements. General patterns of distribution are however clear from the present system.

Polhill (1976) subdivided the Genisteae *s.l.* into four geographically distinct tribes; the Genisteae *s.s.* in the northern hemisphere, the Liparieae in the Cape, the Crotalarieae predominantly in Africa and the Bossiaeae in Australia. The phytogeography of the Crotalarieae was subsequently outlined by Van Wyk & Schutte (1988) and Van Wyk (1991a). Most of the component genera are limited to Africa, with only *Crotalaria* and *Rothia* occurring in the New World. *Argyrolobium* extends through Africa into the Mediterranean and west through Syria, Afghanistan and Pakistan into India. Only *Crotalaria*, *Pearsonia* and *Argyrolobium* are represented in Madagascar. Van Wyk's (1991a) cladistic analysis of the Crotalarieae postulates an alliance between *Melolobium*, *Dichilus*, *Polhillia* and *Argyrolobium*. A comparison of their distribution patterns indicates that *Melolobium* is distributed across all climatic regions of southern Africa.

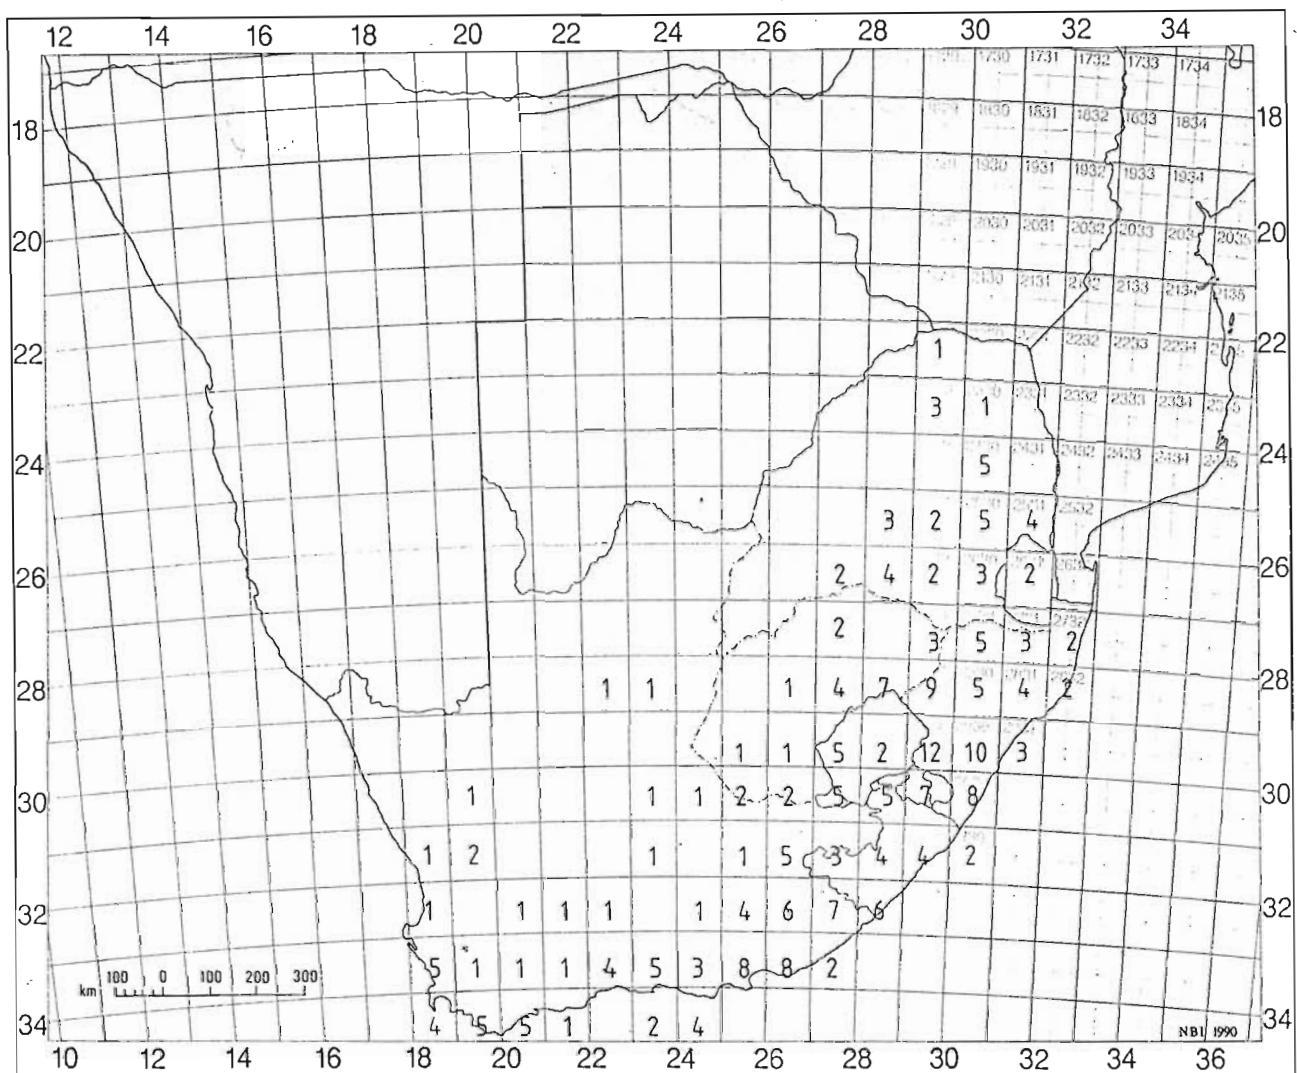

Figure 33. Species density recorded for *Argyrolobium* sect. *Argyrolobium*.

Dichilus is limited to the summer rainfall regions of eastern and central southern Africa and Schutte (1988) suggested an Afromontane origin for it. *Polhillia* is endemic to the south-western Cape and *Argyrolobium* species occur predominantly in the eastern regions of southern Africa.

56% of *Argyrolobium* species occur in South Africa, 21% occur in tropical Africa, 9% occur in north Africa and the Mediterranean and 20% occur in Asia (these percentages exceed 100% due to the occurrence of single species in more than one region). The distribution of *Argyrolobium* is essentially a temperate one. Most species are limited to the eastern seaboard or elevated areas in drier and tropical regions. The drop in species diversity at lower latitudes is a common trend in many southern genera (Beard 1963, Goldblatt 1978, 1983 & 1991, Linder 1983, Oliver 1991, Stirton 1989, Van der Walt & Vorster 1983, Van Wyk 1991a). *Argyrolobium* species densities for South Africa are depicted in Figure 32.

It is informative to compare patterns across *Crotalaria*, *Lotononis* and *Argyrolobium* as similarities exist which help in the explanation of their present distributions. In *Crotalaria* the highest concentrations of species occur in highland areas and although the Afromontane Region is vital to a small forest-linked element, its importance seems to have been principally as a refuge (Polhill 1982). In times of climatic amelioration these refugia provided the genetic core from which more specialized savanna species evolved. Therefore within *Crotalaria*

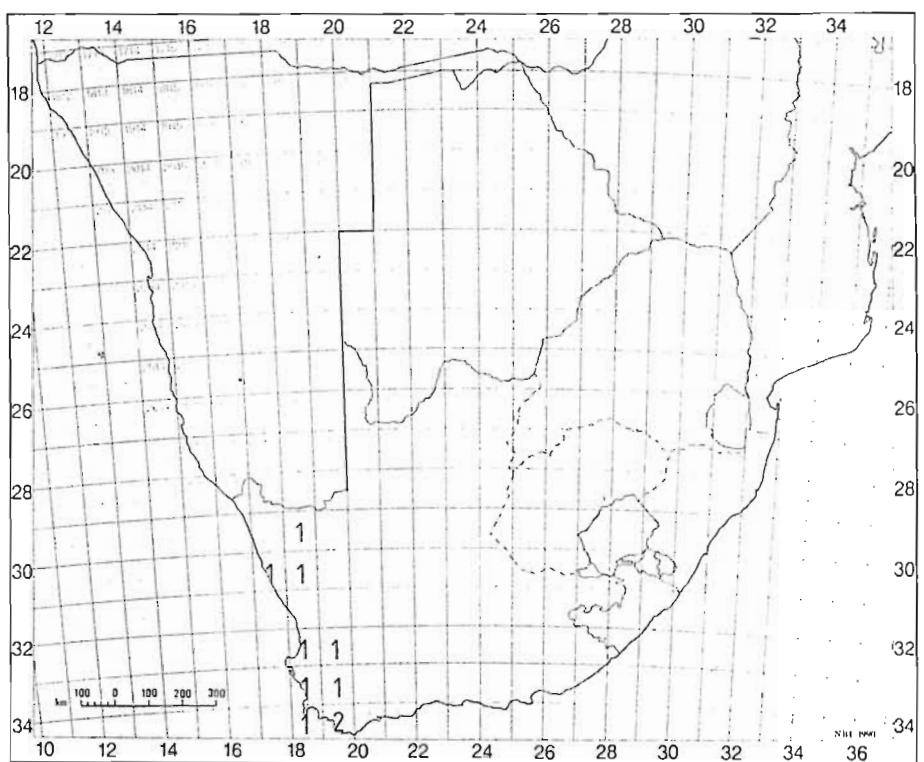

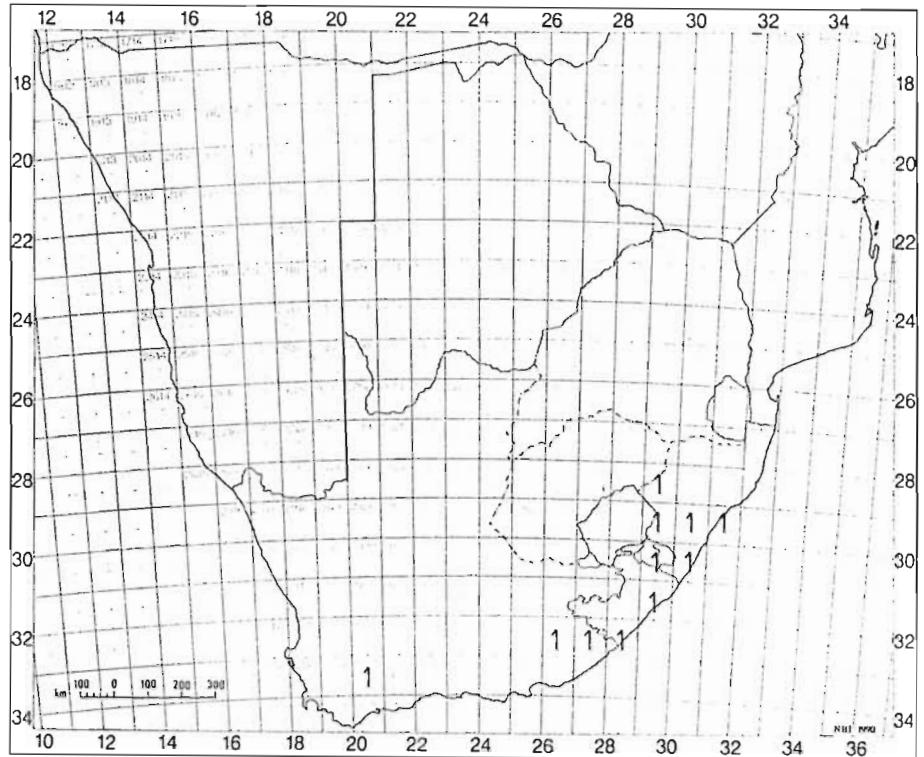

Figure 34. Species density recorded for *Argyrolobium* sect. *Amplexicaule* (A) and *Argyrolobium* sect. *Lunare* (B).

notable disjunctions occur in unspecialised species not closely associated with modern vegetation types. The southern species of *Argyrolobium* which display major disjunctions are *A. rupestre* and *A. tomentosum* both of which appear to have been core species from which similar radiation has taken place. It is not surprising therefore that *Argyrolobium* shows similar trends to *Crotalaria* since *A. tomentosum* and *A. fischeri* Taub. are remarkably similar in habit and distribution to members of *Crotalaria* section *Grandiflorae* which are putative core species (Polhill 1982). Major differences in distributions of the genera relate to the paucity of refuge species and annuals in *Argyrolobium*.

Van Wyk (1991) suggested that the distribution of *Lotononis* supports Goldblatt's (1978) concept of southern Africa as a survival centre for mesic and temperate floristic elements which have subsequently radiated. A comparison of species density between *Lotononis* and *Argyrolobium* shows similar patterns of diversity in Transvaal, Natal, the eastern Cape and the southern Cape coast. No similarities exist in western and central southern Africa due to the absence of annual *Argyrolobium* species in this region. This contrasts with the proliferation of annuals within *Lotononis* for these areas.

Patterns of endemism have been well documented for *Lotononis* (Van Wyk 1991) and *Crotalaria* (Polhill 1982). Our analysis of *Argyrolobium* reveals an intermediate pattern between the aforementioned genera. The main centres of

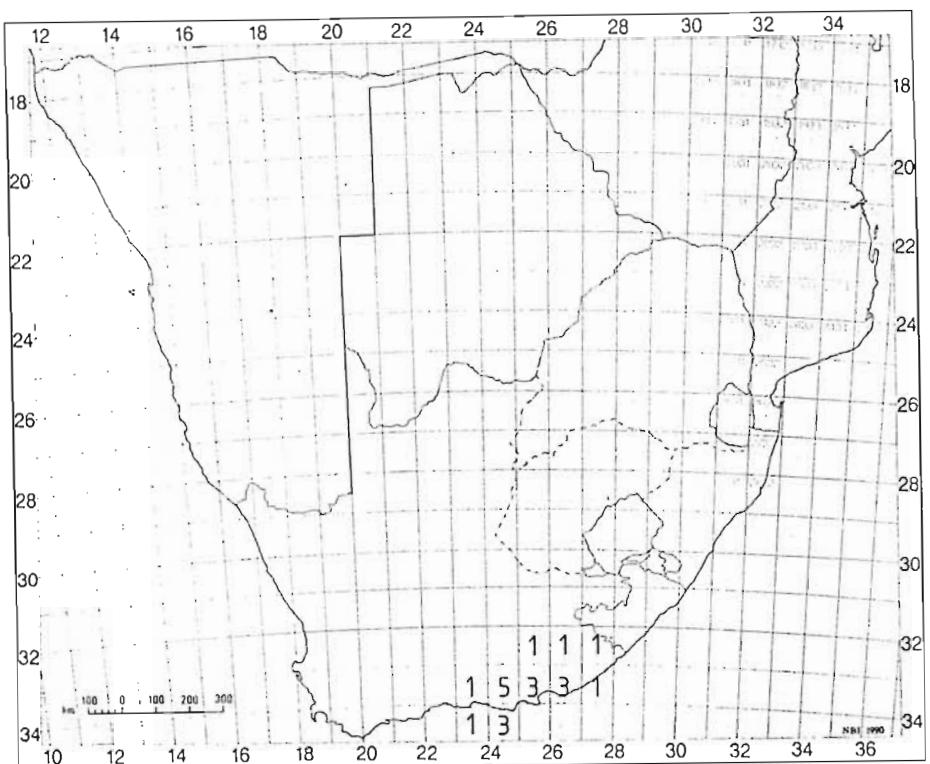

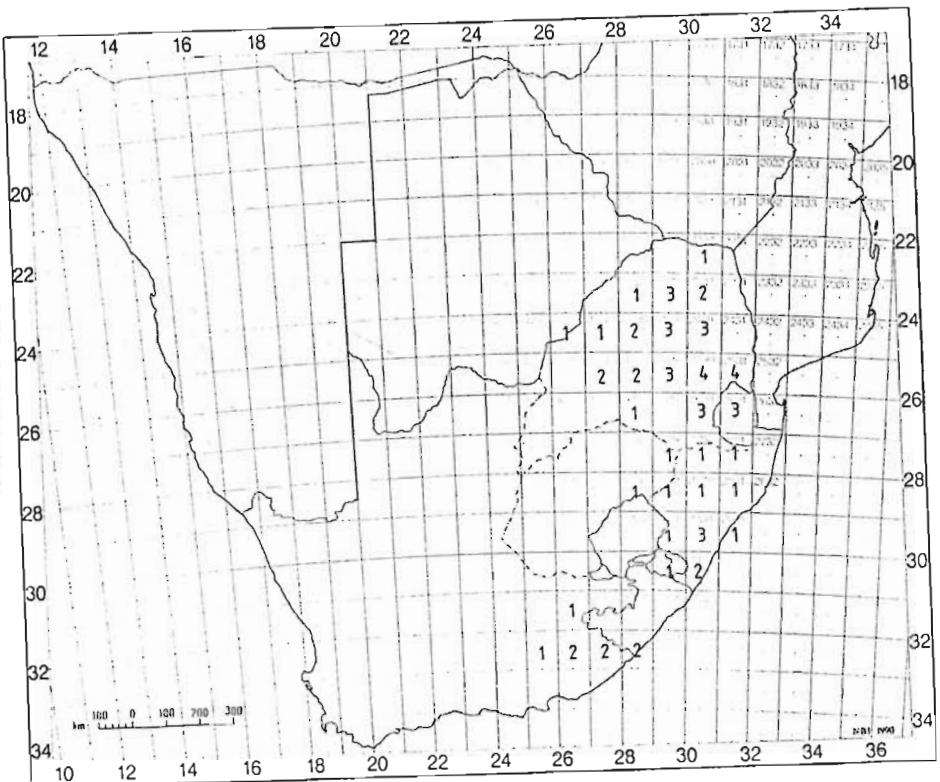

Figure 35. Species density recorded for *Argyrolobium* sect. *Transvaalense* (A) and for *Argyrolobium* sect. *Polyphyllum* (B).

diversity for *Crotalaria* are Tropical African while those of *Lotononis* are southern African. Overlapping areas of high diversity for the genera are southern Angola, central Zimbabwe and Nyika Plateau (Table 5).

Table 5. A comparison of southern African centres of diversity for *Argyrolobium*, *Crotalaria* and *Lotononis* (data from Polhill 1982 and Van Wyk 1991). Area: 1 = Cape Region; 2 = Namaqualand; 3 = eastern Cape; 4 = Natal; 5 = southern Namibia; 6 = Transvaal.

| ARE A. | <i>LOTONONIS</i> | | <i>CROTALARIA</i> | | <i>ARGYROLOBIUM</i> | |
|-----------|------------------|--------|-------------------|--------|---------------------|--------|
| | SPP. | % END. | SPP. | % END. | SPP. | % END. |
| 1 | 58 | 36 | 7 | 3 | 14 | 64 |
| 2 | 24 | 13 | 0 | 0 | 2 | 100 |
| 3 | 30 | 0 | 25 | 0 | 17 | 42 |
| 4 | 36 | 16 | 25 | 0 | 20 | 15 |
| 5 | 20 | 8 | 7 | 3 | 0 | 0 |
| 6 | 23 | 2 | 20 | 1 | 16 | 25 |

Most sections display parochial radiation with the exception of section *Argyrolobium* (Figure 33). It is cogent that this section exhibits cleistogamy which is also common in widespread *Lotononis* species such as *L. tenella* (E. Mey.) Eckl. & Zeyh., *L. pungens* Eckl. & Zeyh. and *L. laxa* Eckl. & Zeyh.

Of the remaining sections:

- 1) *Lunare* is limited to the southern and western Cape (Figure 34). *A. petiolare* is an addition to the growing list of endemics of the Kamiesberg Range (Adamson 1938; Rourke 1990).
- 2) *Polyphyllum* is limited to areas of nonseasonal rainfall in the eastern Cape (Figure 35).
- 3) *Transvaalense* has radiated in the Transvaal and Tropical Africa (Figure 35).
- 4) *Amplexicaule* shows a disjunct distribution with the type species in the eastern Cape and Natal and *A. crinitum* endemic to the Langeberg Centre (Figure 34).

Species which evolved along the Drakensberg usually occur in the eastern Cape, Natal and the eastern Transvaal. Some of these species also extend into the highlands of Zimbabwe and Mozambique (*A. rupestre*, *A. harveyanum*, *A. tuberosum*, *A. tomentosum*).

An interesting anomaly occurs in the Transkei where both *Lotononis* and *Argyrolobium* are poorly represented. The low species diversity in this area is frequently presumed to be the product of undercollecting. However Weimarck (1941) referred to the area as the Kaffraria Interval which he claimed results partly from the inability of the 'Cape element to penetrate xeromorphic biotypes of the

Great Fish River Valley'. This explanation is unsatisfactory as the distributional gap occurs to the north of this valley. A plausible explanation is the discontinuity in sandstones for about 600 km in the Transkei (A.E. Van Wyk 1990). The southernmost outcrops of Natal Group sandstones occur at Port St. Johns and the northern exposures of the Cape Supergroup occur at Suurberg. The intervening landscape is Karoo Sequence interspersed with dolerite intrusions. Although no *Argyrolobium* species are thought to be sandstone endemics these substrates may have provided refugia in the past. Species which conform to the northern limit of the Cape Supergroup sandstones are: *A. barbatum*, *A. collinum*, *A. incanum*, *A. polyphyllum*, *A. pumilum* and *A. trifoliatum*. Species which display a prominent gap in the Transkei are: *A. baptisoides*, *A. molle* and *A. speciosum*.

Thus in conclusion the overall distribution of *Argyrolobium* shows a concentration of species along the eastern seaboard. Highest diversity occurs in afromontane areas of Natal and the eastern Transvaal, a pattern repeated, to some extent, in *Lotononis* (Van Wyk 1991), *Crotalaria* (Polhill 1982) and *Pearsonia* (Polhill 1974). Due to the absence of annuals the genus is represented by a single species (*A. argenteum*) in the dry interior. Species associated with afromontane vegetation are disjunct and probably represent core species.

- 5) Sparse over a large range in several habitats
- 6) Sparse over a large range in one habitat
- 7) Sparse over a restricted range in one habitat.

Despite extensive field work it was impossible to survey all known populations and studies on population dynamics are beyond the scope of this revision. Abridged distributional ranges are presented here (comprehensive distributional data is included in the formal taxonomy and is not repeated in this section).

Locally abundant over a moderate range in several habitats:

A. tomentosum, A. molle, A. stipulaceum, A. amplexicaule, A. argenteum, A. ascendens, A. baptisioides, A. collinum, A. harveyanum, A. lotoides, A. marginatum, A. pseudotuberousum, A. rotundifolium, A. rupestre, A. tuberosum.

Locally abundant in a specific habitat but restricted geographically:

A. frutescens, A. longifolium, A. incanum, A. lunare ssp. lunare, A. megarhizum, A. polyphyllum, A. pumilum, A. speciosum ssp. speciosum, A. transvaalense, A. wilmsii.

Constantly sparse and geographically restricted in specific habitats:

A. aciculare, A. barbatum, A. harmsianum, A. pachyphyllum, A. petiolare, A. rarum, A. velutinum.

CHAPTER 5

CONSERVATION

Hall *et al.* (1980) published the first inventory of threatened plants in southern Africa. This list includes 81 species of Leguminosae and only 35 species of Crotalarieae (*Aspalathus*) are included. A revised version of the list was published for the Fynbos and Karoo Biomes (Hall & Veldhuis 1985). 61 species of *Aspalathus*, one species of *Polhillia*, four species of *Lotononis* and two species of *Rafnia* are listed for the Crotalarieae. Clearly both reports grossly underestimate the threat to tribal diversity.

The lack of entries for *Argyrolobium* is the product of a poor taxonomic understanding of the genus. Hopefully recent systematic research in the Crotalarieae will be incorporated in subsequent analyses to give a more realistic overview of the conservation status of the tribe as a whole.

Rabinowitz (1981) suggested a classification of rare plants into seven basic categories reliant on geographic distribution and local population sizes. A general outline of rarity using these categories is given below.

- 1) Locally abundant over a large range in several habitats
- 2) Locally abundant over a large range in a specific habitat
- 3) Locally abundant over a restricted range in several habitats
- 4) Locally abundant over a restricted range in one habitat

- 5) Sparse over a large range in several habitats
- 6) Sparse over a large range in one habitat
- 7) Sparse over a restricted range in one habitat.

Despite extensive field work it was impossible to survey all known populations and studies on population dynamics are beyond the scope of this revision. Abridged distributional ranges are presented here (comprehensive distributional data is included in the formal taxonomy and is not repeated in this section).

Locally abundant over a moderate range in several habitats:

A. tomentosum, A. molle, A. stipulaceum, A. amplexicaule, A. argenteum, A. ascendens, A. baptisioides, A. collinum, A. harveyanum, A. lotoides, A. marginatum, A. pseudotuberousum, A. rotundifolium, A. rupestre, A. tuberosum.

Locally abundant in a specific habitat but restricted geographically:

A. frutescens, A. longifolium, A. incanum, A. lunare ssp. lunare, A. megarhizum, A. polyphyllum, A. pumilum, A. speciosum ssp. speciosum, A. transvaalense, A. wilmsii.

Constantly sparse and geographically restricted in specific habitats:

A. aciculare, A. barbatum, A. harmsianum, A. pachyphyllum, A. petiolare, A. rarum, A. velutinum.

Argyrolobium is represented by a number of very narrow Cape endemics which are poorly represented in herbaria and should be attributed threatened status.

Populations of some of these species are sparse: *A. barbatum*, *A. crassifolium*, *A. petiolare*, *A. harmsianum*, *A. pachyphyllum*, *A. parviflorum* and *A. rarum*.

All the listed species are endemic to the Cape. Species of summer rainfall areas tend to be more widely distributed however extensive afforestation of the Natal Midlands and the eastern Transvaal escarpment and the invasion of weeds associated with silviculture is drastically reducing the viable populations.

Four species, *A. angustissimum*, *A. splendens*, *A. tenue* and *A. crinitum* are known from single collections and are probably extinct.

CHAPTER 6

CLADISTICS

Recent cladistic analyses are available for the Crotalarieae (Van Wyk & Schutte 1989; Van Wyk 1991) and elsewhere in the family (Crisp & Weston 1987; Lavin 1987; Schrire 1991 and Zandee & Geesink 1987). The technique was applied to the present revision to examine infra-generic groupings of *Argyrolobium*.

The placement of *Argyrolobium* within the Crotalarieae (Van Wyk & Schutte 1989; Van Wyk 1991) conforms with morphological, phytochemical and distributional data and finally resolves the tribal position of the genus. *Dichilus* and *Polhillia* are the closest relatives sharing similar calyces and the occurrence of a-pyridone alkaloids with *Argyrolobium*. They were therefore selected as outgroups in this cladistic survey. The closest ally appears to be *Polhillia* which produces stem-clasping stipules similar to those of *Argyrolobium*.

The data collected for *Argyrolobium* in the present survey was manipulated using the computer programme HENNIG 86 Version 1.5 (Farris 1988). Characters and character states are listed in Table 6. The main data matrix is listed in Table 7.

Table 6. Characters used in the cladistic analysis of *Argyrolobium* using *Dichilus* and *Polhillia* as out-groups (characters 0 1 2 10 12 19 44 unordered).

Data Matrix 2 identical to Matrix 1 except that *A. petiolare* is scored as unknown for floral dimorphism to alleviate potential bias due to undercollecting (characters 26 27 28 29 30 40 42 43 45 49).

A. petiolare

21200 00000 10201 10001 2?000 0???? ?1000 ?0000 ?0??0 ?000?

Initial attempts at analysis were made using the ie command (which generates trees by implicit enumeration) this however failed to resolve the generic matrix. As an

alternative, the mhennig* command was used (which constructs several trees each by a single pass but adds the taxa in a different sequence each time and then applies branch-swapping to each of the trees retaining a single parsimonious tree for each initial tree). The resulting cladograms were manipulated using branch-swapping (bb). Often uniform weighting is too relaxed an assumption and results in an overwhelming array of equally parsimonious topologies or little resolution due to the inclusion of misleading characters (Wheeler 1990). Consequently where more than one equally parsimonious tree was generated from initial manipulations, successive approximation weighting (xs w) (Farris 1969, Carpenter 1988) was applied to reduce the possible number of trees and to accentuate the consistent characters (reduce homoplasy). Following this the character weights were recorded to determine the importance of individual characters. Weights were reset to a value of 1 to negate their influence on tree length and the tree lengths were recalculated and compared with the initial set of trees.

The Dos Equis Command (xx) was used for the examination of character distribution across the cladograms. This allows analysis of the distribution and plausibility of synapomorphies and reversals within the cladograms.

The synapomorphies and reversals were then plotted on the cladograms. In those instances where multiple cladograms were produced, strict consensus trees were generated using the 'nelson' command. These trees are usually longer than trees from which they are derived (Miyamoto 1985) but provide useful information on

unambiguous parts of the cladograms. From the generic analysis a number of monophyletic lineages were identified. These clades were reanalysed individually using a species from the most closely related lineage as the outgroup. Character distribution was scrutinised using the Dos Equis Command (xx).

Results & Discussion

The choice of outgroup scarcely influenced tree topology and did not affect the composition of the main monophyletic clades. The most parsimonious cladograms, generated using *Dichilus* as the outgroup, measured 202 steps with a consistency index of 34 and a retention index of 75. When *Polhillia* was used as the outgroup the most parsimonious trees measured 206 steps with a consistency index of 34 and a retention index of 75. In both instances branch-swapping produced over 100 trees but the strict consensus trees (Figures 36 & 37) retained five monophyletic groups consistently, these were:

Group 1 = *A. amplexicaule* and *A. crinitum*

Group 2 = *A. lunare* and *A. splendens*

Group 3 = *A. crassifolium*, *A. incanum*, *A. parviflorum*, *A. petiolare*, *A. polyphyllum* and *A. trifoliatum*

Group 4 = *A. baptisioides*, *A. frutescens*, *A. longifolium*, *A. megarhhizum*,
A. muddii, *A. speciosum*, *A. transvaalense* and *A. wilmsii*

Group 5 = *A. aciculare*, *A. angustissimum*, *A. argenteum*, *A. ascendens*,
A. barbatum, *A. campicola*, *A. candicans*, *A. collinum*, *A. filiform*,

A. harmsianum, *A. harveyanum*, *A. humile*, *A. lotioides*, *A. marginatum*, *A. molle*, *A. pachyphyllum*, *A. pauciflorum*, *A. pseudotuberosum*, *A. pumilum*, *A. rarum*, *A. rotundifolium*, *A. rupestre*, *A. sericosemium*, *A. stipulaceum*, *A. tomentosum*, *A. tuberosum* and *A. velutinum*.

Examination of the caldograms revealed the placement of *A. petiolare* within Group 3. This is anomalous due to the species elongated petioles, short narrow leaflets and solitary leaf-opposed flowers. In addition *A. petiolare* is geographically disjunct from other members of Group 3. Few specimens of *A. petiolare* are presently available and it may prove to be florally dimorphic which would align it with Group 5. This alternative is also more likely in terms of its morphological and geographic proximity to *A. argenteum*. To negate the influence of potentially miscoded data, characters relating to floral dimorphism in *A. petiolare* were entered as unknown (?) and the revised matrix (Matrix 2) was tested. Thus possible bias introduced by miscoring dimorphic characters was removed. A new set of cladograms was produced with *A. petiolare* being positioned as a close ally of *A. argenteum* and *A. pachyphyllum*. The most parsimonious trees from this set, using *Dichilus* as the outgroup, were 198 steps long (cf. 202 steps) and had consistency and retention indices of 35 and 75 respectively (cf. 34 & 75). The exercise was repeated using *Polhillia* as the outgroup, again *A. petiolare* was positioned as a close ally of *A. argenteum* and

A. pachyphyllum. The most parsimonious trees produced from this manipulation were 202 steps (cf. 206 steps) with consistency indices of 35 and retention indices of 75 (cf. 34 & 75 respectively). Weighted and unweighted strict consensus trees were also consistently shorter for Matrix 2 (Table 8). Without proof of floral dimorphism this alternative arrangement is speculative however in terms of parsimony and inferred relatedness it appears the most likely scenario. In all subsequent manipulations both alternatives were considered for *A. petiolare* to test their plausibility.

Table 8. Statistics of strict consensus trees generated for *Argyrolobium* from matrices 1 (*A. petiolare* scored as florally monomorphic) & 2 (*A. petiolare* scored as unknown for floral polymorphism) (characters 0 1 2 10 12 19 44 unordered).

| Outgroup | Matrix | Unweighted tree | | | Weighted tree | | |
|------------------|--------|-----------------|----|----|---------------|----|----|
| | | length | ci | ri | length | ci | ri |
| <i>Dichilus</i> | 1 | 237 | 34 | 75 | 238 | 66 | 94 |
| <i>Dichilus</i> | 2 | 242 | 35 | 75 | 211 | 66 | 93 |
| <i>Polhillia</i> | 1 | 257 | 34 | 75 | 219 | 65 | 93 |
| <i>Polhillia</i> | 2 | 223 | 35 | 75 | 218 | 65 | 93 |

The character weights following successive approximation weighting are listed in Tables 9 & 10. Characters with a high degree of homoplasy have very low

weights and conversely characters with a low degree of homoplasy have high weights. Highly weighted characters are consistent for both outgroups.

An influential suite of characters within the trees relates to breeding systems and the occurrence of floral dimorphism. Within the Crotalarieae these characters (26; 27; 28; 29; 40; 42; 45; 49) are unique to *Argyrolobium* and are limited to Group 5.

Characters 22 and 25 are synapomorphies which relate to flower and bract morphology of *A. amplexicaule* and *A. crinitum* (Group 1) and display no homoplasy. Character 24, the production of russet and yellow flowers, is synapomorphic for *A. tuberosum* and *A. angustissimum* (Group 5). Likewise characters 38 and 39 are synapomorphic for *A. lunare* and *A. splendens* (Group 2) and refer to diagnostic corolla specializations. Character 5 (adventitious roots) appears to be autapomorphic for upland forms of *A. harneyanum* and consequently is weighted highly.

The separate derivation of lignotubers amongst suffrutescent species of Group 3 (*A. speciosum*, *A. baptisioides*, *A. megarhhizum* and *A. longifolium*) and herbaceous species of Group 5 (*A. tuberosum*, *A. filiform*, *A. pseudotuberousum*, *A. harneyanum* and *A. aciculare*) reduces their weight (characters 6 & 7). Both lineages evolved in seasonal grasslands which are susceptible to fire and

consequently the convergence is not surprising.

Shrubs occur in Groups 4 and 5 and so characters (0 & 2) are somewhat homoplasious in the generic analysis with a low weight. Shrubs appear to have evolved in conjunction with different woody vegetation types. Convergent derivation of these characteristics occurs in fynbos species of Group 4 (*A. incanum*, *A. crassifolium*, *A. parviflorum*, *A. polyphyllum* and *A. trifoliatum*) and in dry scrubland species of Group 5 (*A. argenteum*, *A. barbatum*, *A. pachyphyllum* and *A. petiolare*).

The enlargement and fusion of stipules (characters 8, 9 & 10) are convergent attributes in Groups 1, 2, 3 and 5 and consequently these characters have low weights. Their degree of expression varies but in Group 1, the extreme development and amplexicaul nature of the stipules is clearly synapomorphic. Stipule morphology is also useful in defining Group 2 where the asymmetric stipule bases (character 9) are synapomorphic.

Polhillia

Figure 37. Strict consensus tree of *Argyrolobium* in South Africa using *Polhillia* as the outgroup (Characters 0 1 2 10 12 19 44 unordered) (only the basal topology is illustrated).

The trees generated when *Dichilus* was used as the outgroup are slightly shorter than those produced using *Polhillia* however the position of the branch comprising *A. amplexicaule* and *A. crinitum* is less convincing. These species are very distinct with respect to both vegetative and floral characteristics and this is clearly displayed when *Polhillia* is used as the outgroup (Figure 37). The divergent nature of Group 1 comprising *A. amplexicaule* and *A. crinitum* requires formal recognition in the classification of *Argyrolobium*. The remaining groups are closely allied and the recognition of hierarchical differences on the basis of topology contributes little additional information.

Groups 3, 4 & 5 comprise more than two species and were reanalysed in isolation and rooted using species of the nearest sister group. This allowed a reconsideration of characters which were homoplasious in the global comparison.

Group 5, with 26 species, is the largest monophyletic clade in the generic tree and was manipulated using *A. incanum* as the outgroup. The inclusion of *A. petiolare* had little effect on overall topology or tree length (comparative statistics are presented in Table 11). The strict consensus tree generated following successive approximation weighting was 123 steps when *A. petiolare* was excluded and 125 steps when it was included.

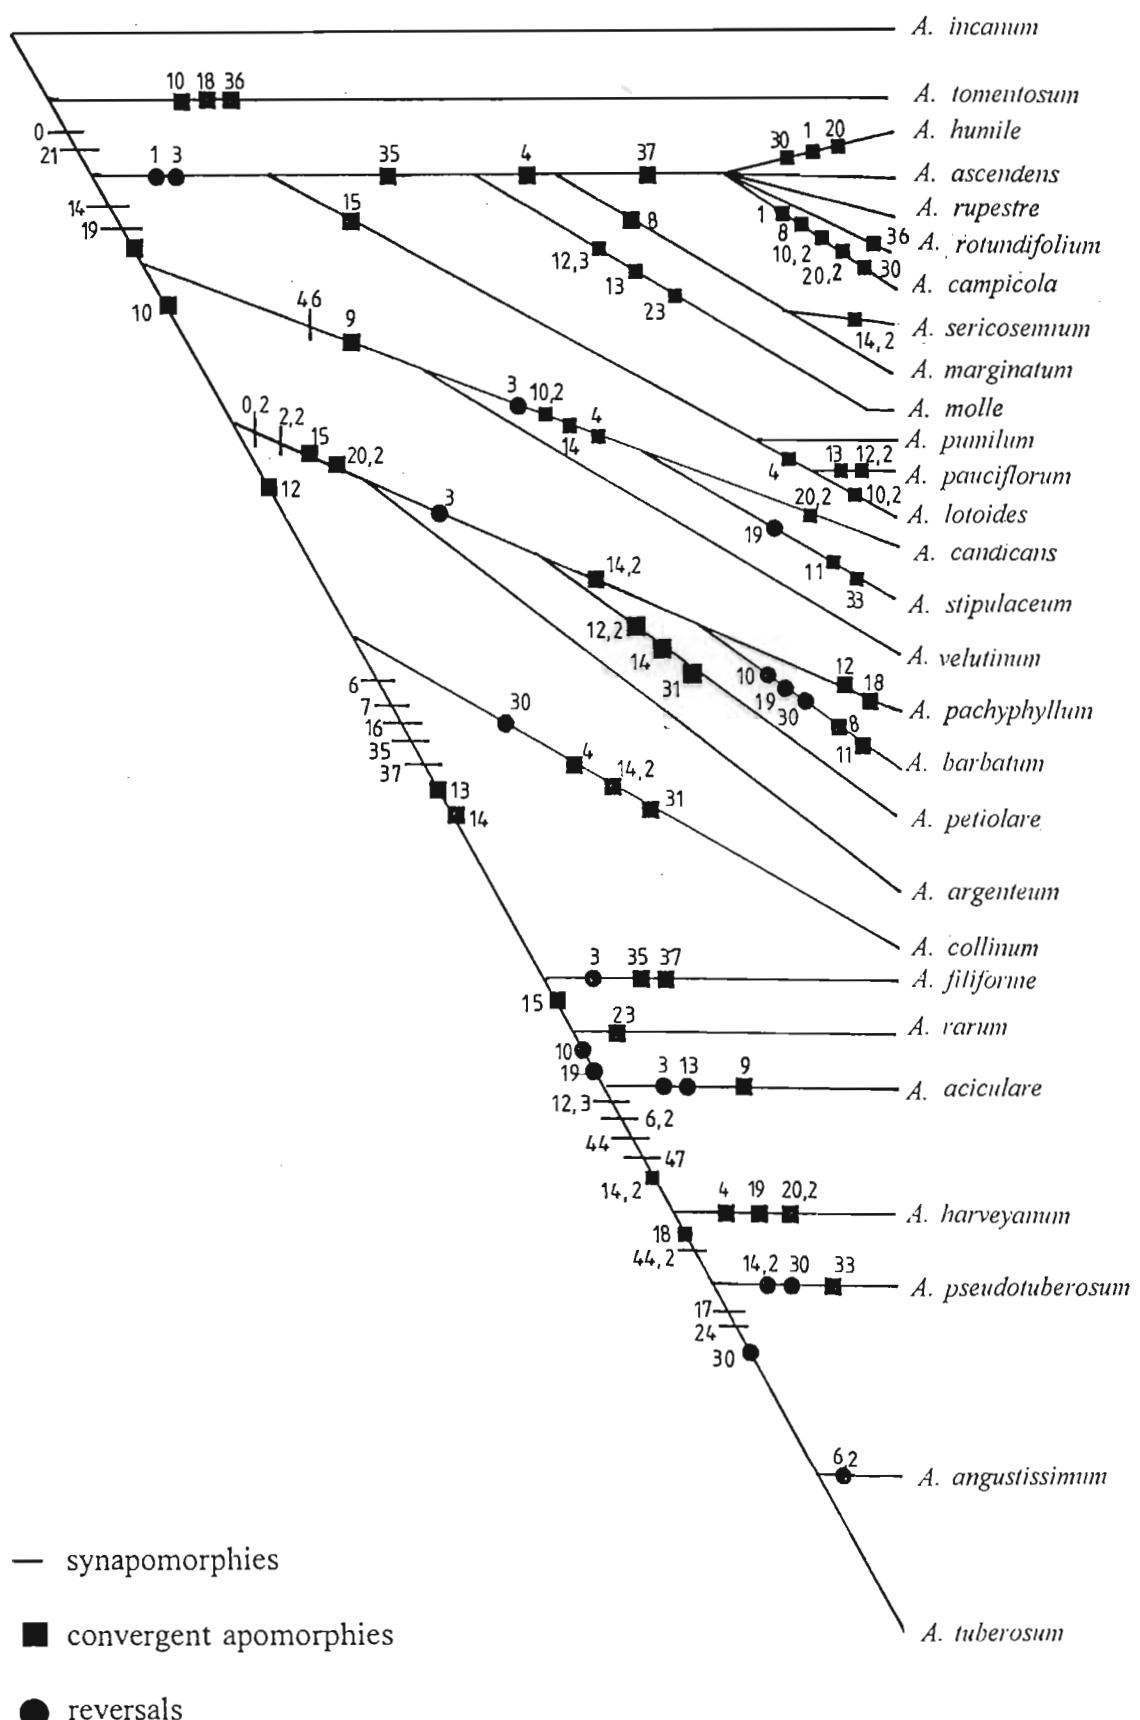

Figure 38. Strict consensus tree of Group 5 polarising aerial perennation and woodiness as specialised and using a hypothetical outgroup based on *A. incanum* (Characters 1 10 12 19 44 unordered) length 123; ci 76; ri 85).

Table 11. Statistics of maximum parsimony cladograms generated for Group 5 (characters 0 1 2 10 12 19 44 unordered; *A. petiolare* included in matrix 2).

| Outgroup | Matrix | Unweighted tree | | | Weighted tree | | |
|-------------------|--------|-----------------|----|----|---------------|----|----|
| | | length | ci | ri | length | ci | ri |
| <i>A. incanum</i> | 1 | 112 | 45 | 64 | 118 | 79 | 86 |
| <i>A. incanum</i> | 2 | 118 | 44 | 63 | 119 | 79 | 87 |

Initial manipulations of Group 5 produced a strict consensus tree in which the shrubs (*A. argenteum*, *A. pachyphyllum*, *A. petiolare*, *A. barbatum*) occur as progenitors to the geophytes (*A. filiform*, *A. harveyanum*, *A. pseudotuberousum*, *A. tuberosum*, *A. angustissimum*). This unlikely scenario requires evolution and subsequent loss of the shrub habit. To accommodate the likelihood that woodiness is specialised, characters 0 & 2 were reconsidered as ordered in a second analysis.

Table 12. Character weights following successive approximation weighting of Group 5 when woodiness and perennation are considered ordered multistate characters (characters 1 10 12 19 44 unordered; group synapomorphies removed).

| Weight | Characters |
|--------|-------------------------------|
| 0 | 11 19 20 21 23 30 31 33 34 36 |
| 1 | 3 4 8 10 13 14 18 |
| 2 | 15 35 |

| | |
|----|----------------------|
| 3 | 1 9 12 |
| 4 | 37 |
| 5 | 0 6 |
| 10 | 2 5 7 16 32 44 46 48 |

The strict consensus tree generated when woodiness is considered apomorphic is the same length as the previous manipulation but the consistency and retention indices are higher (ci 79 vs 42 & ri 87 vs 64). The modified tree depicts four main lines of evolution. Habit and perennation (characters 0 & 2) are highly influential in the cladogram (weighted 5 & 10 respectively) generating a single woody group comprising *A. petiolare*, *A. argenteum*, *A. barbatum* and *A. pachyphyllum*. The basal position of these species contradicts their consistent alliance with the geophytes in the earlier cladograms and is a product of convergent woodiness in the outgroup (*A. incanum*). To overcome this artifactual association between *A. incanum* and shrubs of the ingroup a hypothetical outgroup was generated which retained the coding of *A. incanum* in all characters except those concerned with woodiness and perrenation (0 & 2) which were scored as unspecialized. The cladograms generated from this manipulation are the most parsimonious (Table 13) and accord well with current knowledge of the group.

Table 13. Statistics of cladograms generated for Group 5 when woodiness and perennation (0 & 2) are considered ordered multistate characters using *A. incanum* and a hypothetical outgroup.

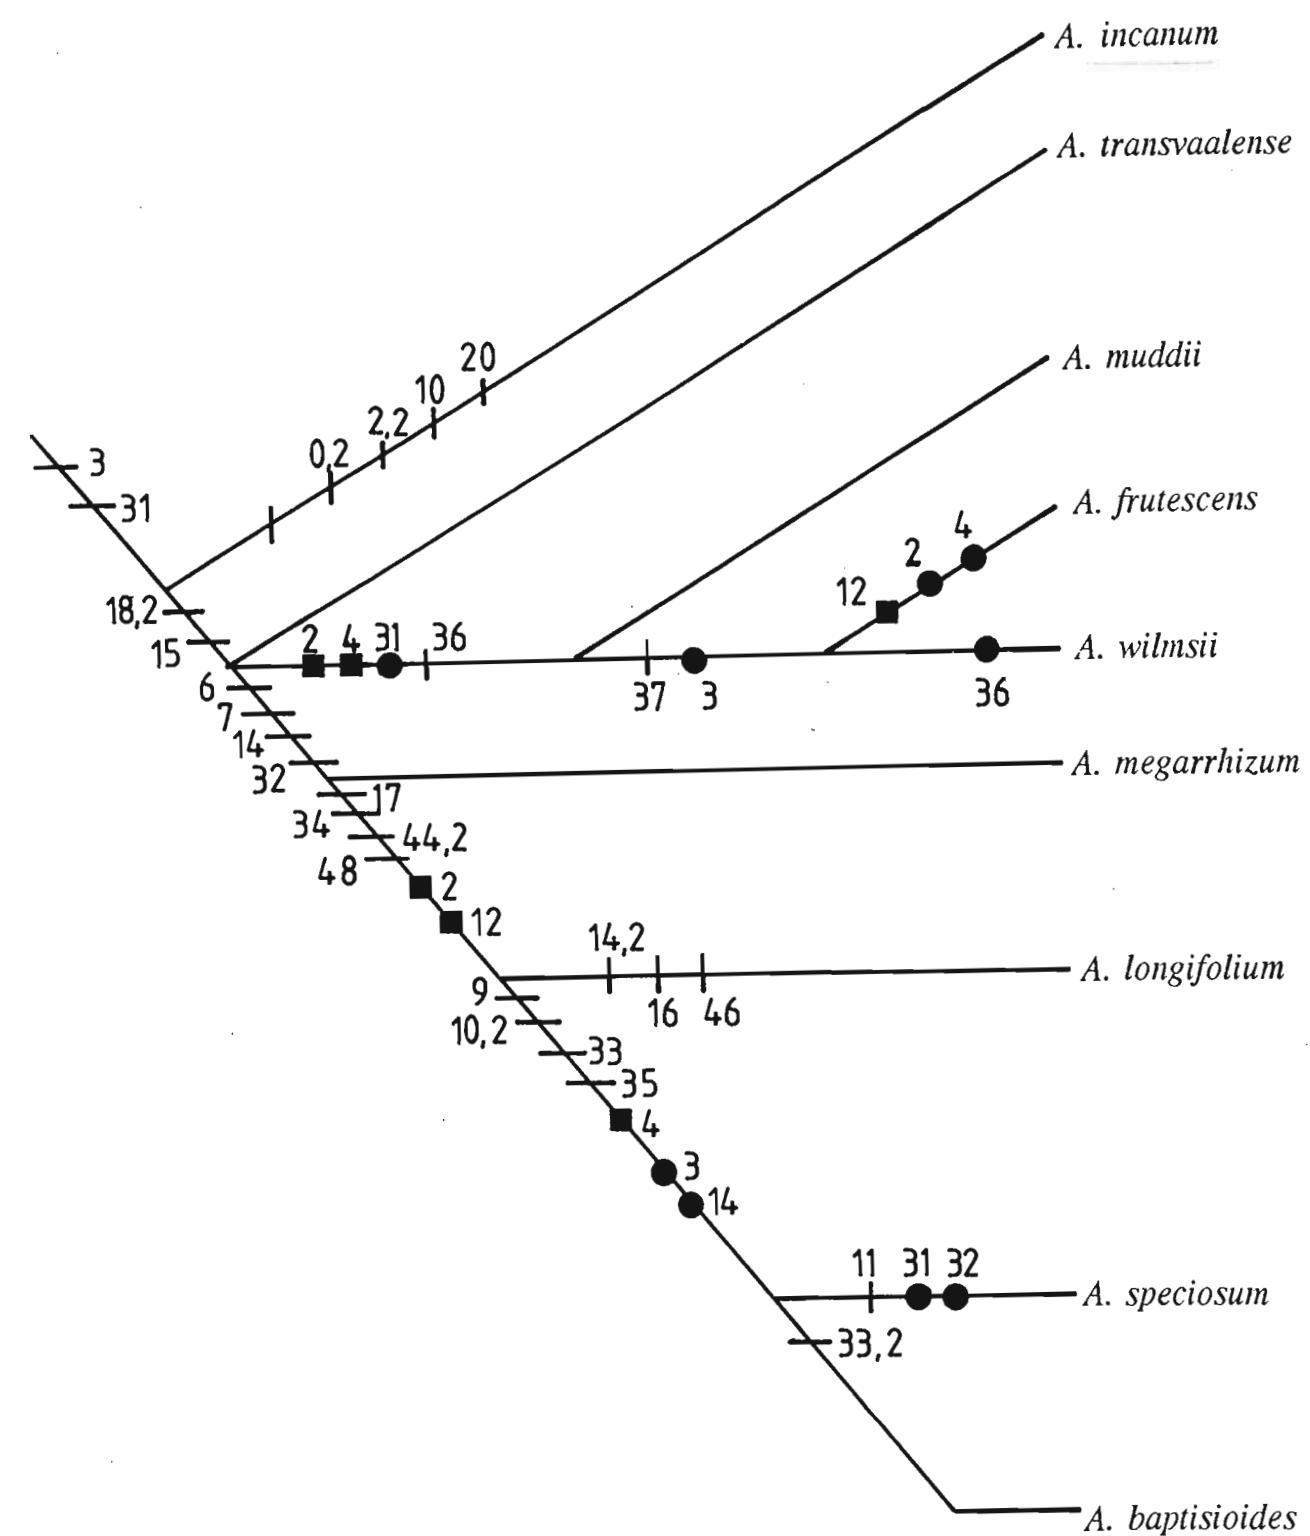

Figure 39. Strict consensus tree of Group 3 using *A. incanum* as the outgroup

(Characters 0 1 2 10 12 19 44 unordered), length 46 steps; ci 94; ri 94.

| Outgroup | Unweighted tree | | | Weighted tree | | |
|-------------------|-----------------|----|----|---------------|----|----|
| | length | ci | ri | length | ci | ri |
| <i>A. incanum</i> | 118 | 44 | 63 | 119 | 79 | 87 |
| Hypothetical | 114 | 44 | 64 | 114 | 77 | 84 |

The strict consensus tree from this manipulation (figure 38) depicts the geophytic and woody species as separate specialized lines. Filiform leaflets and lignotubers (characters 7 & 16) are heavily weighted and the clade containing *A. filiforme* and its allies is particularly robust. These specializations to habit have allowed the invasion of areas subjected to seasonal drought. The lineage also shows a reduction in flower number which is synapomorphic with the woody species but convergent with *A. candicans* and reversed in *A. pseudotuberousum*, *A. tuberosum*, *A. filiform*, *A. aciculare* and *A. angustissimum*.

The widespread suffrutex, *A. tomentosum*, is a generalist species and is basal in the chosen cladogram (figure 38). *A. velutinum*, *A. candicans* and *A. stipulaceum* are consistently grouped due, largely, to the synapomorphic occurrence of turgid fruits.

The mesic herbs which form a complex around *A. rupestre* are closely related and problematic. *A. sericeum* and *A. marginatum* appear to be sister species and were consistently paired in the cladograms. Many of the remaining species are

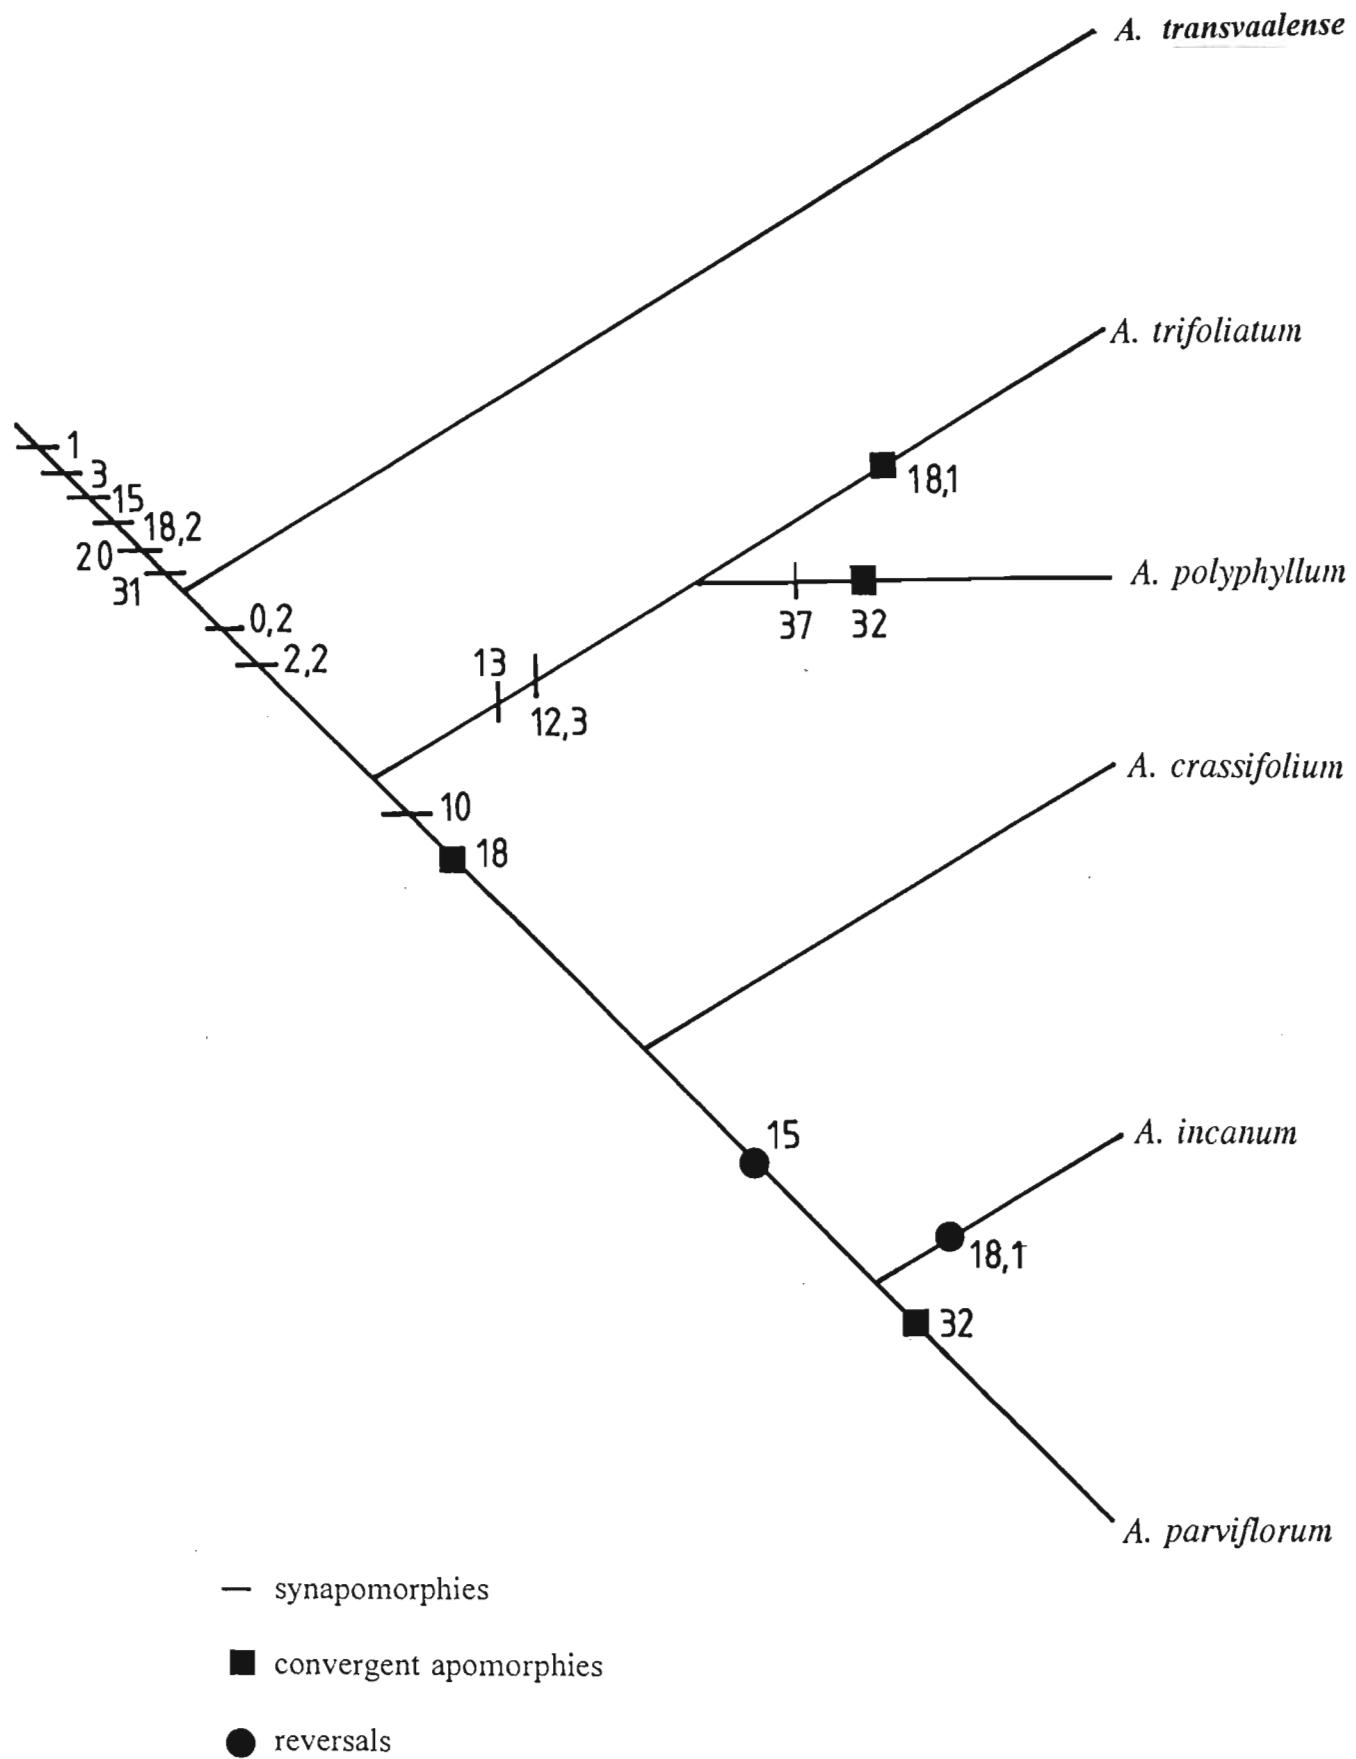

Figure 40. Chosen cladogram of Group 4 using *A. transvaalense* as the outgroup

(Characters 0 1 2 10 12 19 44 unordered), length 14 steps; ci 78; ri 57.

identifiable due to autapomorphies which provide no contribution to topology and consequently resolution within the complex is poor. Wing (35) and keel vestiture (37) are prominent in the *A. rupestris* alliance but are convergent in *A. filiforme* and are therefore only moderately weighted.

Group 3 comprises eight species from which two equally parsimonious trees (46 steps) were generated using implicit enumeration (ie). Following successive approximation weighting the consistency index was improved from 78 to 94 and the retention index was improved from 77 to 94. The two resulting trees differ only in the position of *A. transvaalense* which is either basal to the clade comprising *A. frutescens*, *A. muddii* and *A. wilmsii* or basal to the entire group. Based on our current knowledge either interpretation is acceptable. The strict consensus tree generated from this set was identical to one of the component trees (figure 39). The main dichotomy within the group results from adaptations to seasonal grassland such as lignotubers (characters 6 & 7) and the fusion of the upper calyx sinus in *A. baptisioides*, *A. longifolium* and *A. megarrhizum* (character 32). In terms of floral morphology *A. longifolium*, *A. speciosum* and *A. baptisioides* are specialised with structural modification of the standard bases and accentuation of staminal sheath sinus (characters 34 & 44). In this respect *A. megarrhizum* is plesiomorphic retaining the conservative floral morphology of *A. transvaalense*.

Group 4 comprises shrubs from the eastern Cape which are convergent with *A. argenteum* and its woody allies (Group 5). Implicit enumeration (ie) was used to produce a single most parsimonious tree with a length of 13 steps, a ci of 84 and a ri of 71 (figure 40). Xeric specialisation of *A. incanum* and *A. parviflorum* supports their derived position on the cladogram. *A. polyphyllum* and *A. trifoliatum* are mesic shrubs often associated with forest margins, their coppicing habit and leaf indumentum conforms to that of the outgroup and thus their basal position on the cladogram is not surprising.

Conclusion

This analysis supports the recognition of five main infrageneric taxa. Group 1 is very distinct and is attributed subgeneric status (subgenus *Amplexicaule*). The remaining groups are included in the typical subgenus and are recognised as four closely allied sections. The recognised taxa are listed below with their corresponding groups:

| | | |
|---------|------------------------------|-------------------------------|
| Group 1 | Subgenus <i>Amplexicaule</i> | Section <i>Amplexicaule</i> |
| Group 2 | Subgenus <i>Argyrolobium</i> | Section <i>Lunare</i> |
| Group 3 | Subgenus <i>Argyrolobium</i> | Section <i>Transvaalense</i> |
| Group 4 | Subgenus <i>Argyrolobium</i> | Section <i>Polyphyllum</i> |
| Group 5 | Subgenus <i>Argyrolobium</i> | Section <i>Argyrolobium</i> . |

An overview of extraterritorial species was undertaken and these species fit within

the proposed classification. Tropical African suffrutices are a prominent component of Group 3 and the remaining species belong to Group 5.

Formal Taxonomy

Argyrolobium Eckl. & Zeyh., Enum. Pl. Afr. Austr. 2: 184 (Jan. 1836); Harv.: 67 (1862); Polhill: 145 (1968); Polhill: 332 (1976); Van Wyk & Schutte: 397 (1989); Van Wyk: 282 (1991a), *nom. cons.* Type species: *Argyrolobium argenteum* (N.J. Jacq.) Eckl. & Zeyh. (*Crotalaria argentea* Jacq.) (*typ. cons.*).

Lotophyllus Link, Handb. 2: 156 (1831) *nom. rej.* Type species: *Lotophyllus argenteus* Link [now *Argyrolobium linnaeanum* Walp.]

Chasmone E. Mey. Comm. Pl. Afr. Austr. 1(1): 71 (5 Feb.--5 Jun. 1836). Lectotype species (selected here): *Chasmone argentea* (Jacq.) E. Mey. [now *Argyrolobium argenteum* (Jacq.) Eckl. & Zeyh.].

Gamochilum Walp. in Linn. 13: 509 (1839). Lectotype species (selected here): *Gamochilum sericeum* (E. Mey.) Walp. [now *Argyrolobium trifoliatum* (Thunb.) Druce].

Trichasma Walp. in Linn. 13: 510 (1839). Lectotype species (selected here): *Trichasma ciliatum* (Sprgl.) Walp. [now *Argyrolobium tomentosum* (Andr.) Druce].

Perennial herbs, suffrutices or shrubs. *Leaves* alternate, digitately trifoliolate, petiolate or subsessile; stipules 2, free or variously connate, subulate to foliaceous, bases often amplexicaul. *Inflorescence* solitary-flowered, racemose or pseudo-umbellate, usually terminal or leaf-opposed; bracts cymbiform to

lanceolate, variously attached to the peduncle or pedicels; bracteoles 2, setaceous to lanceolate, variously attached to the pedicels or calyces. *Flowers* often dimorphic. *Calyx* bilabiate, upper lip usually 2-lobed, lower lip usually 3-lobed. *Corolla* yellow becoming russet or russet and yellow; standard ovate, obovate or suborbicular, adaxial surface variously sericeous, base cordate to cuneate, claw short; wings oblong to obovate, sometimes distally sericeous, lunate-lamellate sculpturing usually present; keel cymbiform, apex blunt, abaxial suture and distal lamina sometimes sparsely sericeous. *Stamens* 10, monadelphous or pseudodiadelphous, sheath often deeply split adaxially; anthers dimorphic, alternating, 5 large, oblong and basifixed, 5 small, ovate and dorsifixed. *Ovary* *subsessile*, narrowly oblong usually densely sericeous, ovules numerous; style arcuate, glabrous; stigma capitate. *Fruit* subsessile, densely sericeous, oblong or linear, flat, sub-torulose or turgid, many seeded. *Seed* irregular, suborbicular or reniform, 1–3 mm in diameter, hilar rim raised or flat, hilar tongue usually present, rarely arillate (*A. ascendens*), testa smooth.

The genus includes about 91 species 45 of which occur in South Africa. Species are distributed from the Cape Province to the Mediterranean and West into the highlands of India.

The genus is closely allied to other Old World members of the Crotalarieae with bilabiate calyces in which the lower lip comprises three lobes and the upper lip

two lobes. It is distinguished from these genera by its broad-based (often amplexicaul) stipules (not auriculate as in *Melolobium*, inconspicuous as in *Dichilus*, or adnate to the petioles as in *Polhillia*). Its wing and keel petals are of similar length to the lower calyx lip and shorter than the standard (unlike *Lebeckia* and *Dichilus*). Bracteoles are present in all species of *Argyrolobium* although they may be setaceous or vestigial in some specimens (usually absent in *Polhillia*). The occurrence of pseudopeduncles is limited to *Polhillia* and a few species of *Argyrolobium* (notably *A. argenteum*, *A. filiforme* and *A. aciculare*). The fusion of the stamens into a closed sheath is not consistent throughout the genus and is therefore not a reliable diagnostic character.

KEY TO SOUTH AFRICAN SPECIES OF *ARGYROLOBIUM*

1. Stipules fused for more than half their length 2
 - Stipules free or fused for less than half their length 5

2. Bracts as long as or longer than the calyx, cymbiform; flowers monomorphic 3
 - Bracts shorter than the calyx, ovate; flowers dimorphic 4

3. Stipules 4-lobed *A. crinitum* (pg. 120)
 - Stipules 2-lobed *A. amplexicaule* (pg. 116)

4. Inflorescence pedunculate *A. campicola* (pg. 192)
 - Inflorescence subsessile *A. candicans* (pg. 215)

5. Flowers monomorphic 6
 - Flowers dimorphic (fruits with reduced calyces) 26

6. Suffrutices 7
 - Shrubs or herbs 15

7. Leaves monomorphic; exsiccatae green, silver or brown 8
 - Leaves dimorphic; exsiccatae black 12

8. Leaves sparsely sericeous, green 9
Leaves velutinous, silver *A. wilmsii* (pg. 139)
9. Standard petal ovate to suborbicular 10
Standard petal obovate *A. frutescens* (pg. 132)
10. Calyx lobes prominent 11
Calyx lobes vestigial *A. megarrhizum* (pg. 142)
11. Plants forming short, dense clumps (less than 0.5 m tall); petioles prominent *A. muddii* (pg. 137)
Plants virgate (taller than 0.5 m); petioles short
..... *A. transvaalene* (pg. 133)
12. Plants tall (> 0.6 m excluding the inflorescences), virgate, well branched above *A. longifolium* (pg. 144)
Plants short (< 0.4 m excluding the inflorescences), branched basally
..... 13
13. Standard obovate to oblanceolate, plain yellow
..... *A. baptisioides* (pg. 145)
Standard suborbicular, veins reddish 14

14. Plants slender, often decumbent; peduncles prominent; limited to the eastern Cape *A. speciosum* ssp. *speciosum* (pg. 147)
- Plants robust, erect, peduncles short; limited to Natal and the Transvaal *A. speciosum* ssp. *megaphyllum* (pg. 150)
15. Shrubs 16
- Herbs 23
16. Leaves dimorphic 17
- Leaves monomorphic 18
17. Upper leaves small, 5--9(--17) x 2--4 mm, on brachyblasts
- *A. polyphyllum* (pg. 163)
- Upper leaves large, 10--24 x 8--14 mm, not borne on brachyblasts
- *A. trifoliatum* (pg. 160)
18. Leaflets with reticulate abaxial ribs . . *A. parviflorum* (pg. 170)
- Leaflets lacking abaxial ribs 19
19. Petioles longer than terminal leaflets *A. petiolare* (pg. 229)
- Petioles shorter than terminal leaflets 20
20. Stipules connate in the basal third *A. barbatum* (pg. 232)

- Stipules free 21
21. Leaflets strongly conduplicate, crescent-shaped
A. *pachyphyllum* (pg. 231)
- Leaflets seldom conduplicate or crescent-shaped 22
22. Leaflets densely hairy, coriaceous A. *incanum* (pg. 168)
Leaflets sparsely hairy, usually glabrous adaxially, membranous
. 23
23. Slender, well branched shrubs; leaflets shorter than 12 mm;
inflorescences less than 5-flowered A. *crassifolium* (pg. 165)
Sparingly branched shrubs; leaflets longer than 16 mm; inflorescences
many-flowered A. *trifoliatum* (pg. 160)
24. Leaflet margins revolute; fruits compressed
A. *splendens* (pg. 129)
Leaflet margins flat; fruits torulose 25
25. Plants robust; limited to the Caledon area
A. *lunare* ssp. *lunare* (pg. 123)
Plants slender; widespread
A. *lunare* ssp. *sericeum* (pg. 125)

| Seeds with asymmetrical hilar tongues | 37 |
| 37. Wing petals without sculpturing . . . | <i>A. rotundifolium</i> (pg. 185) |
| Wing petals sculptured | 38 |
| 38. Upper petioles shorter than stipules | 39 |
| Upper petioles longer than stipules. | 45 |
| 39. Individual flowers russet & yellow | <i>A. tuberosum</i> (pg. 256) |
| Flowers uniformly yellow (often becoming russet with age) | 40 |

40. Leaflets linear, less than 2 mm broad *A. aciculare* (pg. 244)
Leaflets ovate to elliptic, broader than 2 mm 41
41. Inflorescence 1-2--flowered, leaf-opposed . . . *A. humile* (pg. 178)
Inflorescence many-flowered, terminal *A. marginatum* (pg. 197)
42. Stipules shorter than 6 mm *A. rupestre* ssp. *rupestre* (pg. 188)
Stipules longer than 6 mm 43
43. Bracts small (usually less than 4 mm long), bracteoles minute
. *A. lotoides* (pg. 205)
Bracts large (usually greater than 6 mm long), bracteoles 4--7 mm long
. *A. marginatum* (pg. 197)
44. Flowers solitary; legume compressed 45
Flowers seldom solitary; legume inflated *A. velutinum* (pg. 223)
45. Leaflets oblong to oblanceolate, glabrous adaxially 46
Leaflets obovate, densely sericeous *A. collinum* (pg. 234)
46. Stamens pseudodiadelphous *A. harveyanum* (pg. 245)
Stamens monadelphous *A. harmsianum* (pg. 237)

47. Individual flowers russet and yellow 51
Individual flowers uniformly yellow 48
48. Chasmogamous inflorescences sessile 49
Chasmogamous inflorescences pedunculate 52
49. Chasmogamous flowers solitary 50
Chasmogamous flowers in fascicles *A. filiforme* (pg. 239)
50. Upper leaves with reduced petioles *A. harveyanum* (pg. 245)
Upper leaves with pronounced petioles *A. rarum* (pg. 242)
51. Flowers large; lower calyx lip 15--17 mm long
A. angustissimum (pg. 254)
Flowers small; lower calyx lip less than 12 mm long
A. tuberosum (pg. 256)
52. Plants hairy; upper leaflets with prominent petioles
A. pauciflorum (pg. 210)
Plants glabrescent; upper leaflets with short petioles or subsessile
A. pseudotuberosum (pg. 252)

SPECIES DESCRIPTIONS

A. tenue Walp. is incompletely known and is therefore not included. From its distribution and fruiting isotype the species appears to be closely allied to section *Polyphyllum* however it is distinguished from other species in that section by its oblanceolate leaflets and short petioles. A flowering type specimen is housed at K but, due to the paucity of flowers, our request to dissect one was denied.

Sectio 1. Amplexicaule T.J. Edwards sect. nov. habens flores monomorphos, stipulas connatas foliceasque, et bracteas cymbiformes excedentes flores longitudine.

A distinct section based on the enlarged, amplexicaul stipules and the prominent floral bracts. The fruits of *A. crinitum* are unknown but *A. amplexicaule* has inflated fruits which are convergent to those of some

species in section *Argyrolobium*.

Type species: *A. amplexicaule* (E. Mey.) Dümmer.

Suffrutescences, forming clumps, branched basally; stems erect, annual, pilose, becoming glabrous; roots ligneous, perennial. *Leaves* pilose; leaflets ovate to obovate, apex rounded to acute, apiculate; petiole adaxially canaliculate, stipules amplexicaul, distal margin entire to deeply lobed. *Inflorescence* pedunculate; bracts large, narrowly ovate; bracteoles narrowly oblanceolate to filiform. *Calyx* pilose, deeply bilabiate. *Corolla* yellow; standard suborbicular, adaxial surface sericeous, claw, canaliculate; wings oblong, glabrous, claw prominent; keel cymbiform, claw prominent. *Stamens* monadelphous, sheath completely fused above. *Fruit* pilose, inflated.

1. *Argyrolobium amplexicaule* (E. Mey.) Dümmer Lond. J. Bot.: 222 (1913); Harms: 177-178 (1917). Type: Between Zandplaat & Komgha, *Drège s.n.* (K!, lecto. selected here).

Lotus amplexicaulis E. Mey.: 92 (1835); Harv.: 158 (1862). Type: as above.

Argyrolobium pilosum Harv.: 71 (1862). Type: Transkei Country, *Bowker 106* (TCD!, lecto. selected here).

Suffrutex up to 400 mm tall, forming clumps, branched basally; stems annual, pilose, becoming glabrous. *Leaves* pilose; leaflets 25--40 x 6--17 mm, ovate to obovate, apex rounded to acute, apiculate; petiole 7--14 mm long, adaxially canaliculate; stipules 15--45 x 12--40 mm, amplexicaul, apex often emarginate.

Inflorescence (3--)7--45-flowered, terminal; peduncle 5--70 mm long; bracts 15--24 x 3--7 mm, cymbiform; bracteoles 3--6 x 0.5--1.5 mm, oblanceolate to filiform. *Calyx* pilose, deeply bilabiate; upper lobes 8--13 mm long, upper sinus 2.5--4 mm deep, lower lip 9--16 mm long, lobes acute, 4--6 mm long. *Corolla* yellow; standard suborbicular, 10--14 x 8--12 mm, adaxial surface sericeous, claw, canaliculate, 3 mm long; wings oblong, 8--11 x 3.5--4 mm, glabrous, claw 1.5--2 mm long; keel cymbiform, 7--9 x 3.5--4 mm, claw 1.5--2.5 mm long.

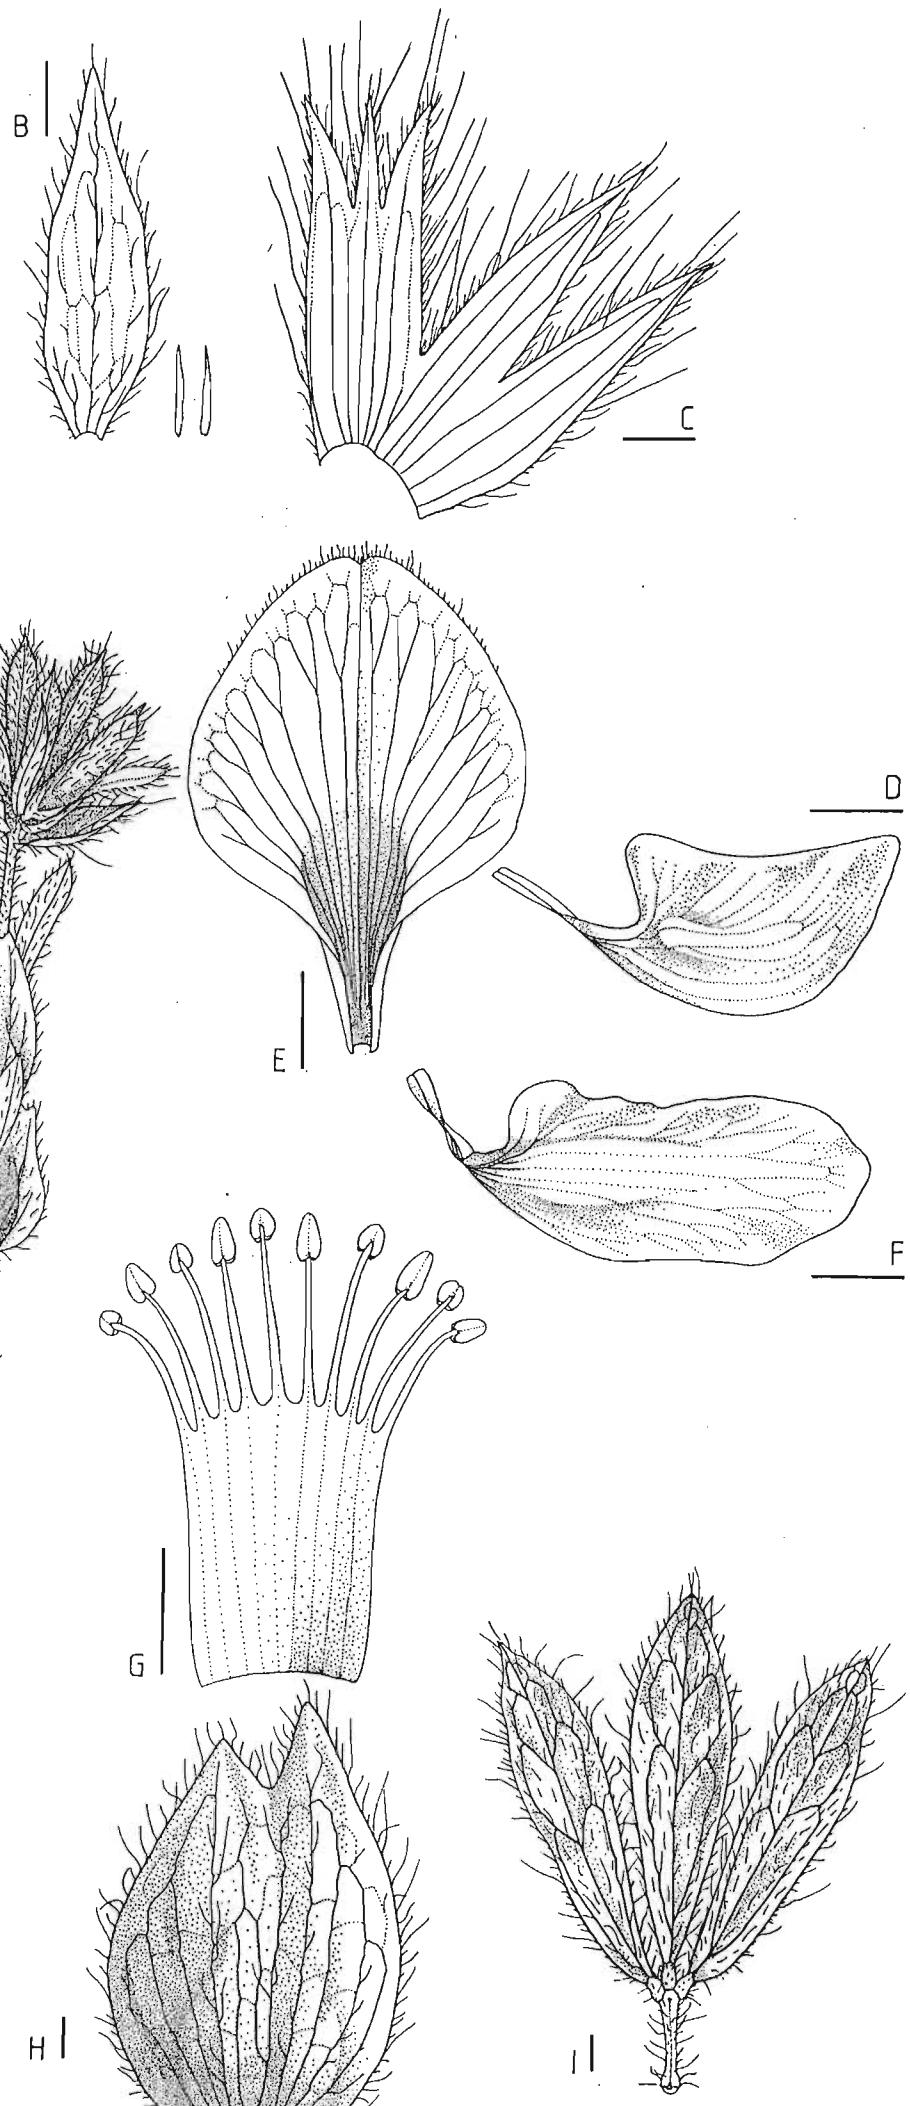

Stamens monadelphous, sheath completely fused above. *Ovary* narrowly oblong, 4--5 mm long; style 3--4 mm long. *Fruit* pilose, inflated, 15--25 x 4-5 mm. *Seed* suborbicular to reniform, 2 mm in diameter, slightly compressed.

A. amplexicaule is distinctive due to its large connate stipules and dense, pseudo-umbellate inflorescences. Its closest ally, *A. crinitum*, differs in having four-lobed stipules and spicate inflorescences.

A. amplexicaule is often found in association with *Lotononis corymbosa* (E. Mey.) Benth. forming floral guilds. Plants occur in Coastal Thornveld, Highland Sourveld, Dohne Sourveld (Figure 43). Wood (1910) reports the occurrence of

cleistogamy in this species but our investigation revealed no evidence of floral dimorphism and we suspect the earlier record is erroneous.

Argyrolobium amplexicaule. A. Flowering branch (bar = 15 mm); B. bract and bracteoles (bar = 2 mm); C. calyx (bar = 2 mm); D. keel (bar = 2 mm); E. standard (bar = 2 mm); F. wings (bar = 2 mm); G. androecium (bar = 2 mm); H. stipules (bar = 2 mm); I. leaf (bar = 2 mm). Voucher: *Edwards* 763.

2. *Argyrolobium crinitum* (E. Mey.) Walp. in Linnaea 13: 506 (1839); Walp.: 630 (1843); Benth.: 340 (1844); Harv.: 68 (1862). Type: Cape, Swaartberge, Trado, *Drège* 6627 (P!).

Chasmone crinita E. Mey.: 71 (1836). Type: as above.

Suffrutex up to 600 mm tall, forming clumps, branched basally; stems annual, rufous-pilose. *Leaves* pilose; leaflets 30--50 x 14--23 mm, ovate to obovate, apex rounded; petiole 10--20 mm long, adaxially canaliculate; stipules 20--40 x 18--24 mm, amplexicaul, apex usually 4-lobed. *Inflorescence* elongate, terminal; bracts 13 x 5 mm, ovate; bracteoles 2 x 0.75 mm, filiform. *Calyx* pilose, deeply bilabiate; upper lobes 6 mm long, upper sinus 4.5 mm deep, lower lip 8 mm long, lobes acute, 3 mm long. *Corolla* yellow; standard suborbicular, strongly reflexed, 8 x 8 mm, adaxial surface sparsely sericeous medially, claw, canaliculate, 4 mm long; wings oblong, 9 x 4 mm, glabrous, claw 4 mm long, sculpturing in the lower basal and upper basal zones; keel cymbiform, 7 x 4 mm, claw 5 mm long.

Stamens monadelphous, sheath split above. *Ovary* narrowly oblong, 9 mm long, densely rufo-sericeous, 6-seeded; style 4 mm long. *Fruit & seed* unknown.

14

A. crinitum is a distinctive species with large, 4-lobed stipules. It was collected

Figure 42

Argyrolobium crinitum. A. Vegetative branch (bar = 20 mm); B. calyx (bar = 2 mm); C. wing (bar = 2 mm); D. keel (bar = 2 mm); E. standard (bar = 2 mm); F. calyx, pedicel and bract (bar = 2 mm). Voucher: *Drège* s.n.

once, in False Macchia, and is probably extinct (Figure 43). Its distinctive morphology led Meyer (1835) to suggest that it may represent a new genus. This comment must be viewed in the light of his placement of *A. amplexicaule* within *Lotus*. These species are closely allied having similar leaves, stipules and vestiture. Only a single flower of *A. crinitum* was available for examination and so details of inflorescence structure were taken from Meyer (1836). The calyx has a truncate base and the petals have well developed claws. The fusion of the filaments, the dimorphic anthers and the calyx morphology however support its placement within *Argyrolobium*.

3320 (Montagu): Swaartberge, Trado, (--DD), *Drège* 6627 (P).

Sectio 2. Lunare T.J. Edwards sect. nov. Herbae perennes, suffrutices vel frutices, foliolis conduplicatis, petiolis prominentibus, stipulis asymmetrice ovatis vel dimidiatis (subulatis in *A. petiolari*), floribus monoformis, antheris saepe pilosis.

Type species: *A. lunare* (L.) Druce.

Herbaceous to shrubby, often decumbent, sparsely branched. *Leaves* variously sericeous, leaflets narrowly elliptic to ovate, apex acute to emarginate, petioles prominent; stipules asymmetrically lanceolate to ovate, base obliquely cordate to obtuse. *Inflorescence* 1--3-flowered, peduncle usually well developed, leaf-

opposed; bracts lanceolate to cordate; bracteoles lanceolate. *Calyx* sericeous, deeply bilabiate. *Corolla* yellow becoming russet; standard orbicular, adaxial surface sparsely sericeous, base obtuse to cordate, claw prominent; wings oblong, usually with lunate-lamellate sculpturing in the upper basal and upper central zones, claw prominent; keel cymbiform, upper margin markedly ciliate, claw prominent. *Stamens* monodelphous, vexillary filament sometimes largely free; anthers often slightly hairy proximally. *Ovary* densely sericeous; style basally hairy. *Fruit* compressed, sometimes torulose, sericeous.

This section is characterised by its monomorphic flowers and a combination of other characters. Most species are suffutescent or herbaceous with very prominent petioles and peduncles.

The section is limited to the Cape. Hairy anthers are unique to this alliance but do not occur throughout.

A. lunare has been grouped with the North African and Mediterranean species in section *Eremolobium* (Bentham 1844; Harvey 1862). In our opinion the small alliance surrounding *A. lunare* is exclusive to the Cape Floral Kingdom.

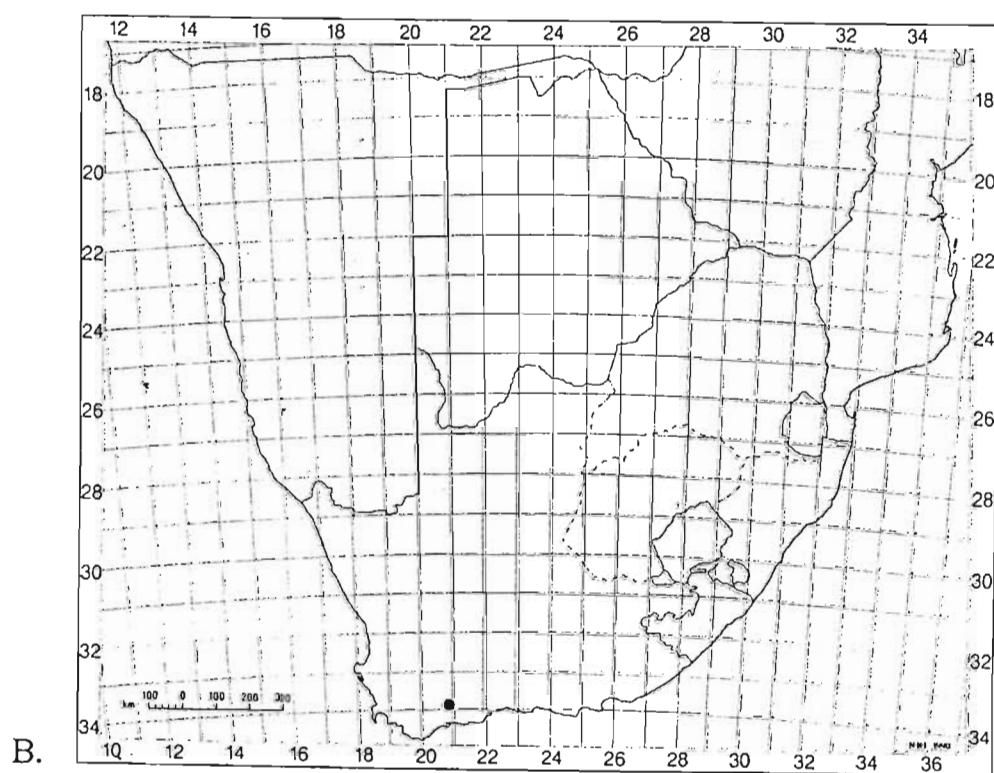

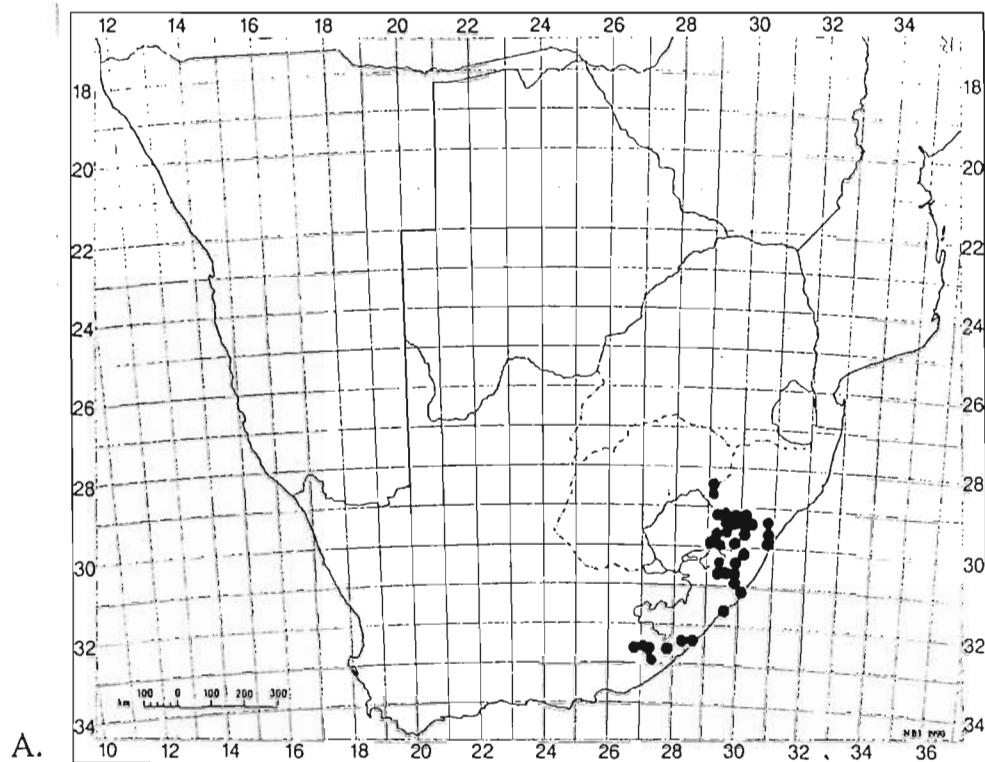

Figure 43. Recorded distribution of A. *A. amplexicaule* & B. *A. crinitum*.

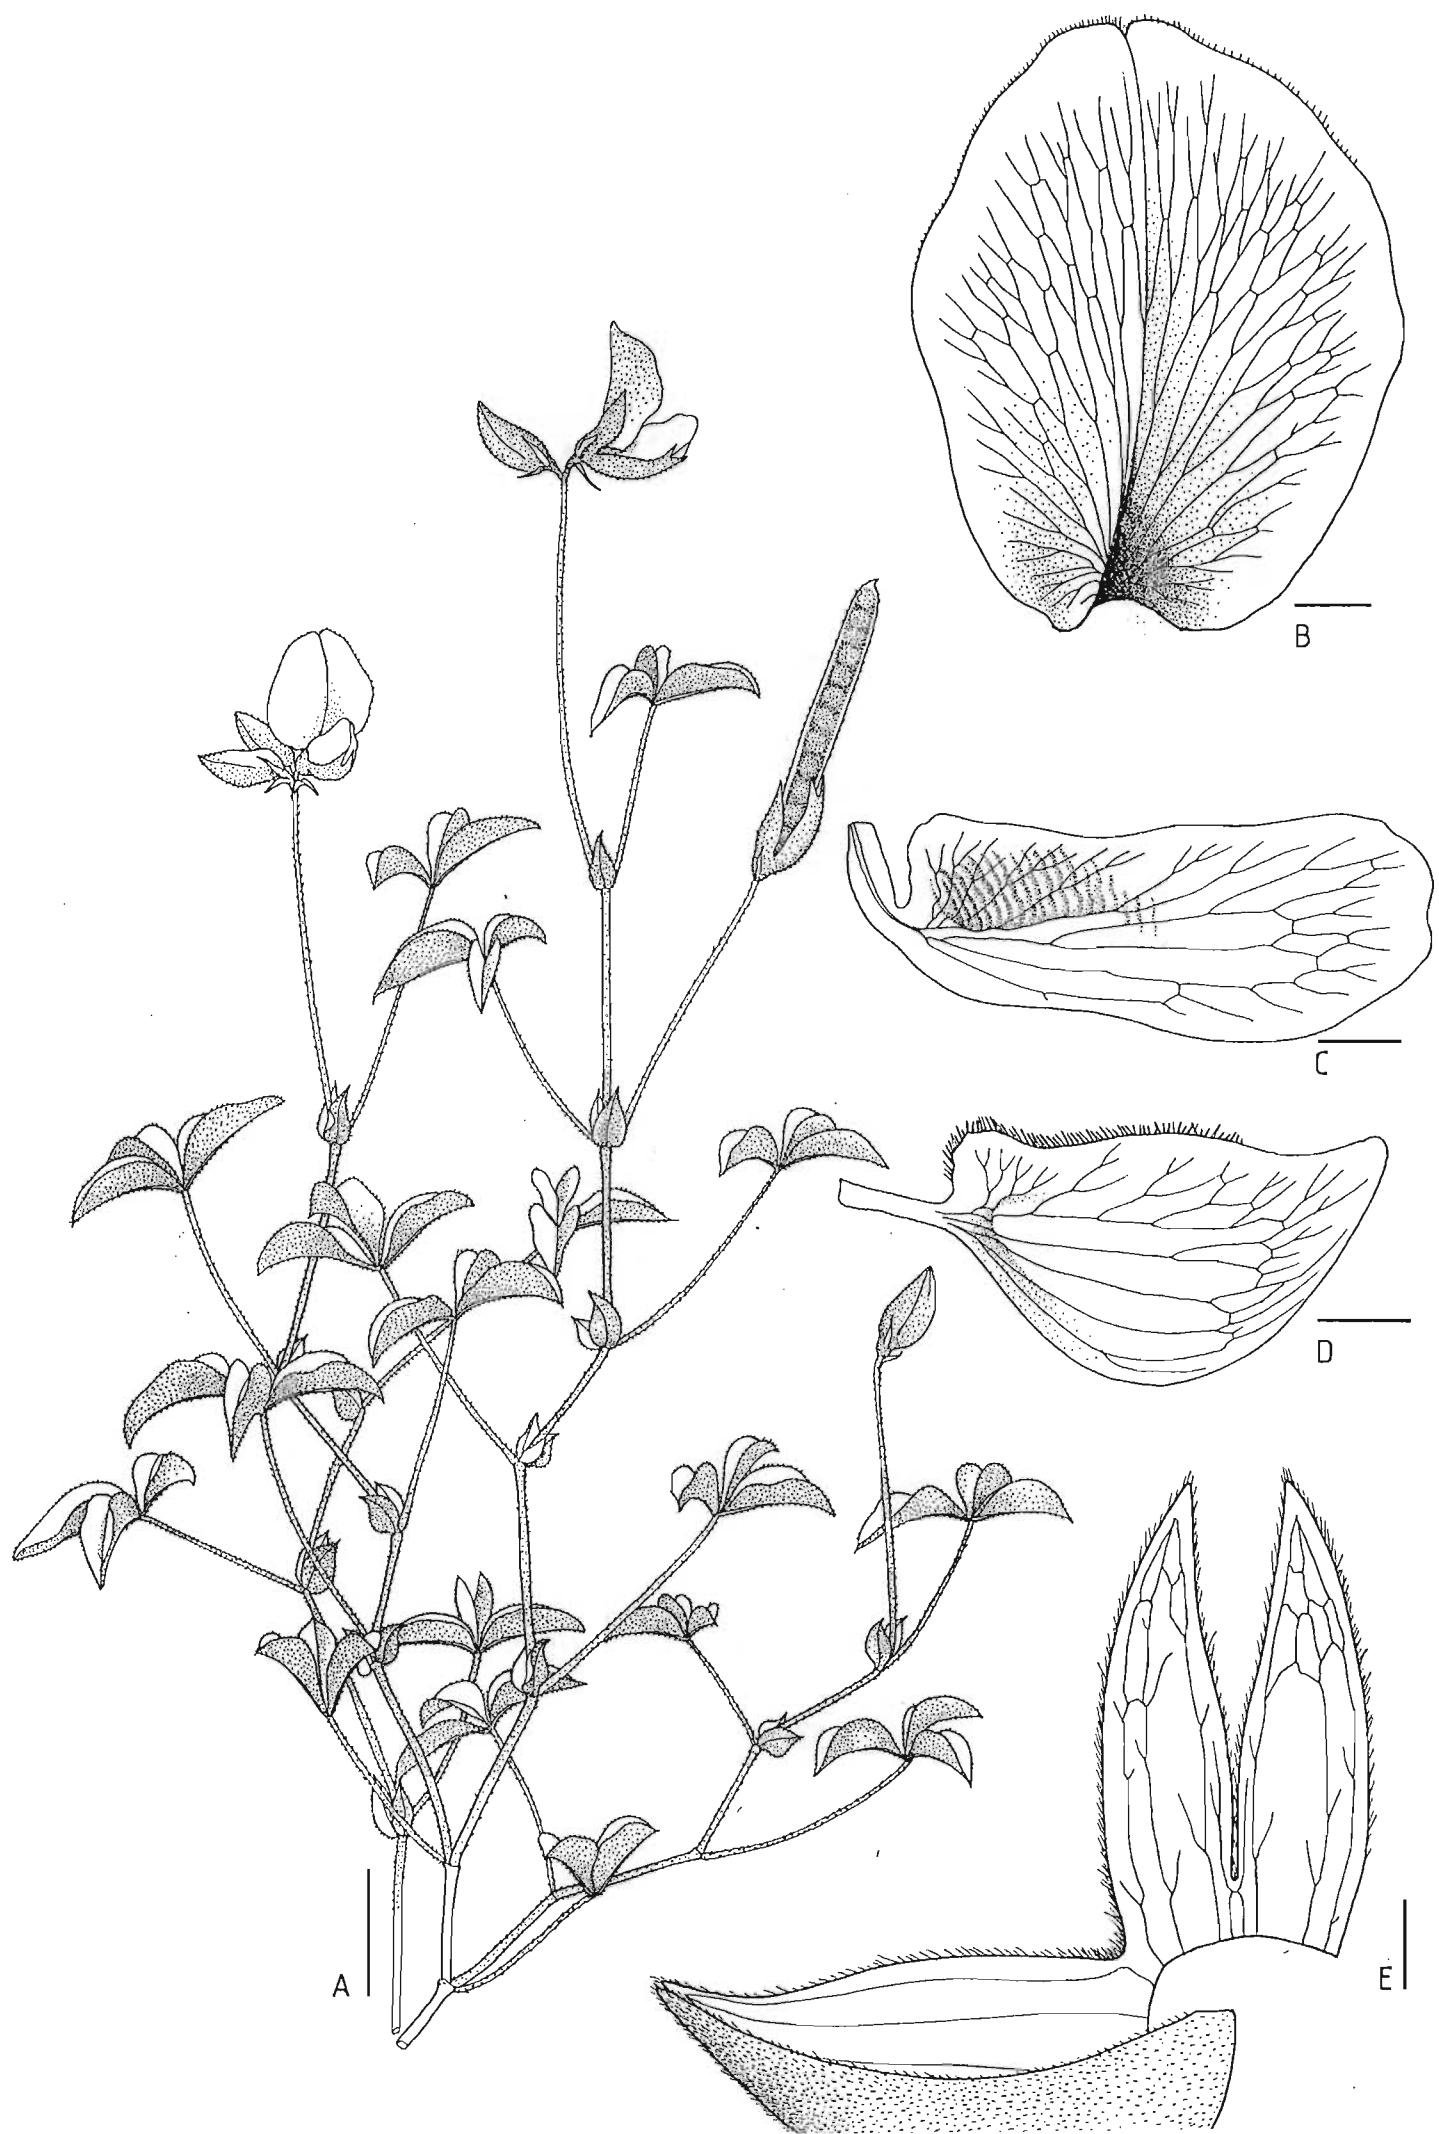

evolution of torulose fruits in the Leguminosae provides added resistance to seed predation and is frequently convergent. In addition torulose fruits do not occur in *A. splendens* which is clearly a close ally of *A. lunare*.

3a. *Argyrolobium lunare* (L.) Druce subsp. *lunare* in Rep. Bot. Exch. Brit. Isles, 1913, 3: 414 (1914).

Crotalaria lunaris L.: 715 (1753), non *Crotalaria lunaris* Burm. f. Type: Cape of Good Hope, *Crotalaria* no. 5, Herb. Clifford 357 (BM!).

Suffrutescences, 0.2–0.3 m tall, decumbent, sparsely branched, stems weakly perennial, shortly sericeous, plants forming small clumps. *Leaves* abaxially densely sericeous, adaxially sparsely sericeous to glabrous; leaflets elliptic to narrowly ovate, 14–30 x 5–14 mm, apex acute, petiole 20–40 mm long; stipules lanceolate to ovate, 3–10 x 3–8 mm, base obliquely cordate to obtuse.

Inflorescence 1–3-flowered, peduncle well developed, 30–150 mm, leaf-opposed; bracts lanceolate to cordate, 4–6 x 1–2 mm; bracteoles lanceolate, 3–5 x 1–1.5 mm. *Calyx* shortly sericeous, upper lip 10–12 mm long, sinus 8–9 mm deep; lower lip 14–17 mm long, lobes 3–5 mm long, medial lobe linear. *Corolla* yellow becoming russet; standard orbicular, 13–17 x 13–16 mm, adaxial surface sparsely sericeous, base obtuse to cordate, claw 3–4 mm long; wings oblong, 11–15 x 4–5 mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw 3–4 mm long; keel cymbiform, 14–15 x 6–7 mm, upper margin ciliate,

claw 3–4 mm long. *Stamens* monodelphous, vexillary filament often largely free; anthers dimorphic, often slightly hairy proximally. *Ovary* narrowly oblong, 9–10 mm long, densely sericeous; style 5–6 mm long, basally hairy. *Fruit* torulose, sericeous, 60–70 x 4–5 mm. *Seed* suborbicular, dark brown, 2–3 mm, hilar tongue prominent.

This species is closely allied to *A. splendens* (Meisn.) Walp. which differs in its shorter petioles, coriaceous leaves with strongly revolute margins and evenly compressed fruits.

Argyrolobium lunare is closely associated with the Table Mountain Series of the Cape System (Figure 48). It is variable in both vegetative and floral characters (Figures 44, 45, 46).

This subspecies (Figure 48) is limited to the Caledon Area and is distinguished by its robust reproductive and vegetative organs.¹⁵

16

Within *A. lunare* morphometric variation shows some degree of geographic pattern. Terete-leaved forms are restricted to the Cederberg, Olifantsrivierberge, Koue Bokkeveld and Piketberg (Figure 48). However the variability of leaf shape within the species forms a continuum.

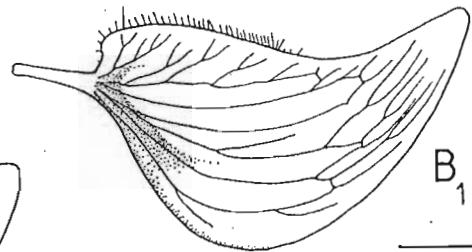

Small-flowered specimens are widespread and often sympatric with the remaining morphs. Large-flowered individuals are restricted to the south but no discontinuity

between these extremes exists. The species occurs in Coastal Macchia and Coastal Renosterbosveld.

The distribution of the subspecies repeats a pattern found in *Aspalathus carnosa* Berg. Small-flowered forms of the latter also occur on Table Mountain while large-flowered forms are restricted around Caledon (Dahlgren 1963). This pattern may relate to pollinators since it is likely that the species share vectors.

¹⁷

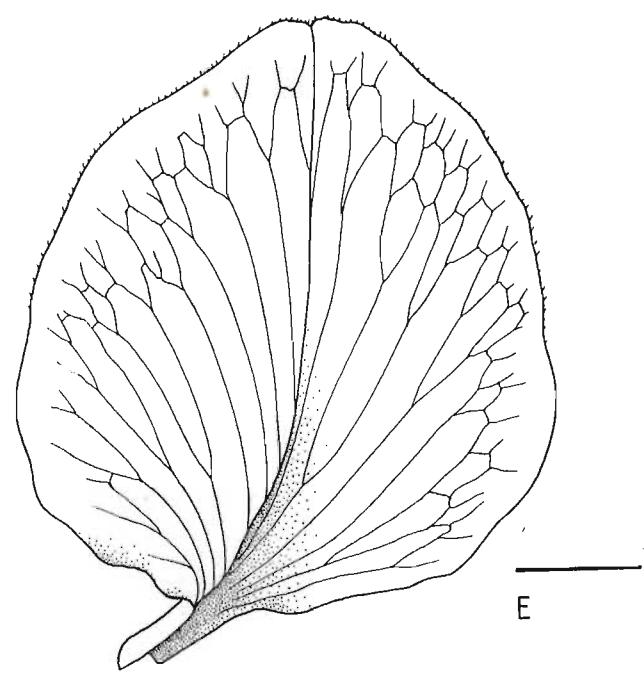

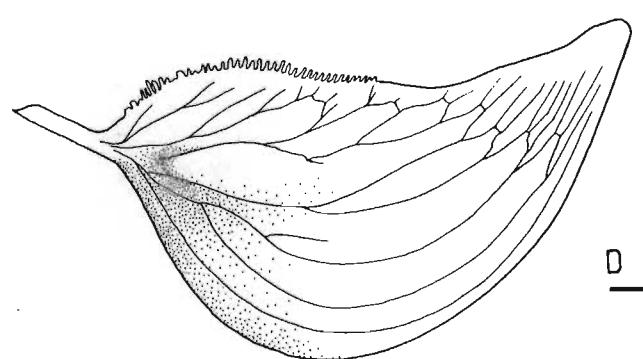

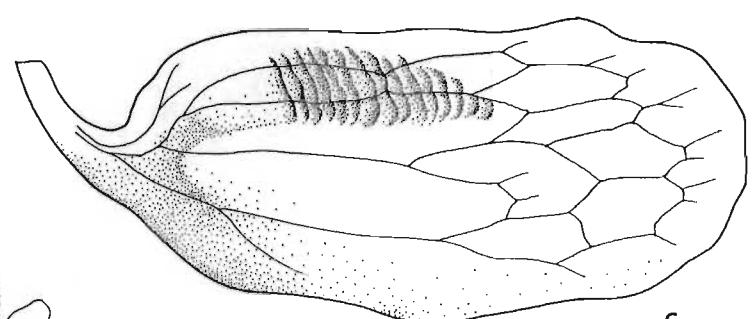

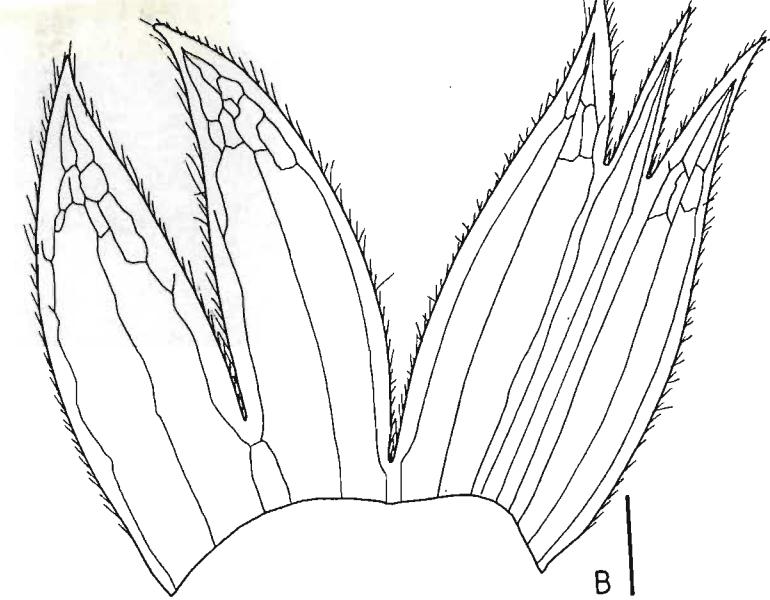

4. *Argyrolobium splendens* (Meisn.) Walp. Repert. Bot. Syst. 2: 845 (1843); Benth.: 348 (1844); Harv.: 76 (1862). Type: Cape Province, mountain sides around Klein Rivier, Swellendam, Krauss 927 (B†; NY!, lecto. selected here; G!, MO!, W!, isolecto.).

Chasmone splendens Meisn.: 78 (1843). Type: as above.

Herb, 0.2–0.3 m tall, erect, well branched, stems shortly sericeous, plants forming clumps. Leaves abaxial surface densely sericeous, adaxially sparsely sericeous becoming glabrous; leaflets oblong to obovate, 20–35 x 7–14 mm, strongly revolute, apex rounded, apiculate, petiole 5–12 mm long; stipules ovate,

Figure 46

A. lunare ssp. *lunare*; A₁ keel, A₂ wing, A₃ androecium, A₄ large anther, A₅ small anther, A₆ calyx (bars = 2 mm). Voucher: De Vos 155.
A. lunare ssp. *sericeum*; B₁ keel, B₂ wing, B₃. androecium, C₁ keel, C₂ wing, C₄ large anther, C₅ small anther, C₆ calyx (bars = 2 mm). Vouchers: B = Gray 37; C = Borchardt 565.

7--9 x 4 mm, base obliquely cordate. *Inflorescence* fasciculate, 1--3-flowered, peduncle well developed, 25--60 mm long, leaf-opposed; bracts lanceolate, 4--5 x 1.5--2 mm; bracteoles lanceolate, 3 x 1 mm. *Calyx* shortly sericeous, upper lip 10--11 mm long, sinus 7--9 mm deep; lower lip 11--12 mm long, lobes 3--4 mm long, medial lobe linear. *Corolla* yellow; standard orbicular, 12--14 x 9--12 mm, adaxial surface sparsely sericeous, base obtuse, claw 3 mm long; wings oblong, 11--12 x 3 mm, with lunate-lamellate sculpturing in the upper central zone, claw 3 mm long; keel cymbiform, 9--10 x 4 mm, upper margin shortly ciliate, 3 mm long. *Stamens* monodelphous; anthers dimorphic. Ovary weakly arcuate, 8--9 mm long, densely sericeous; style 4--5 mm long, basally hairy. *Fruit* compressed, sericeous, 38--42 x 5 mm. *Seed* not seen.¹⁸

The obvious alliance between this species and *A. lunare* (Meisner 1843; Harvey 1862) contradicts the use of torulose fruits as a sectional character (Bentham 1844; Harvey 1862). *A. splendens* is known only from the type collection which was gathered on the coastal fold mountains which flank the Kleinrivier. Distributionally the species is close to its ally *A. lunare* which is distinguished by its torulose fruits, longer petioles and non-revolute leaf margins (Figure 46).

Sectio 3. Transvaalense T.J. Edwards sect. nov. Suffruticosa, foliis monomorphis et dimorphis, habitu ramoso, exsiccatis viridibus et nigresentibus, floribus monomorphic.

Species of this section do not turn black when pressed, have monomorphic flowers and leaves and a suffrutescent habit. The section is centred in the eastern Transvaal, South Africa but includes four Tropical African species (*A. friesianum* Harms, *A. fischeri* Taub., *A. macrophyllum* Harms and *A. aequinoctiale* Welw. ex Baker).

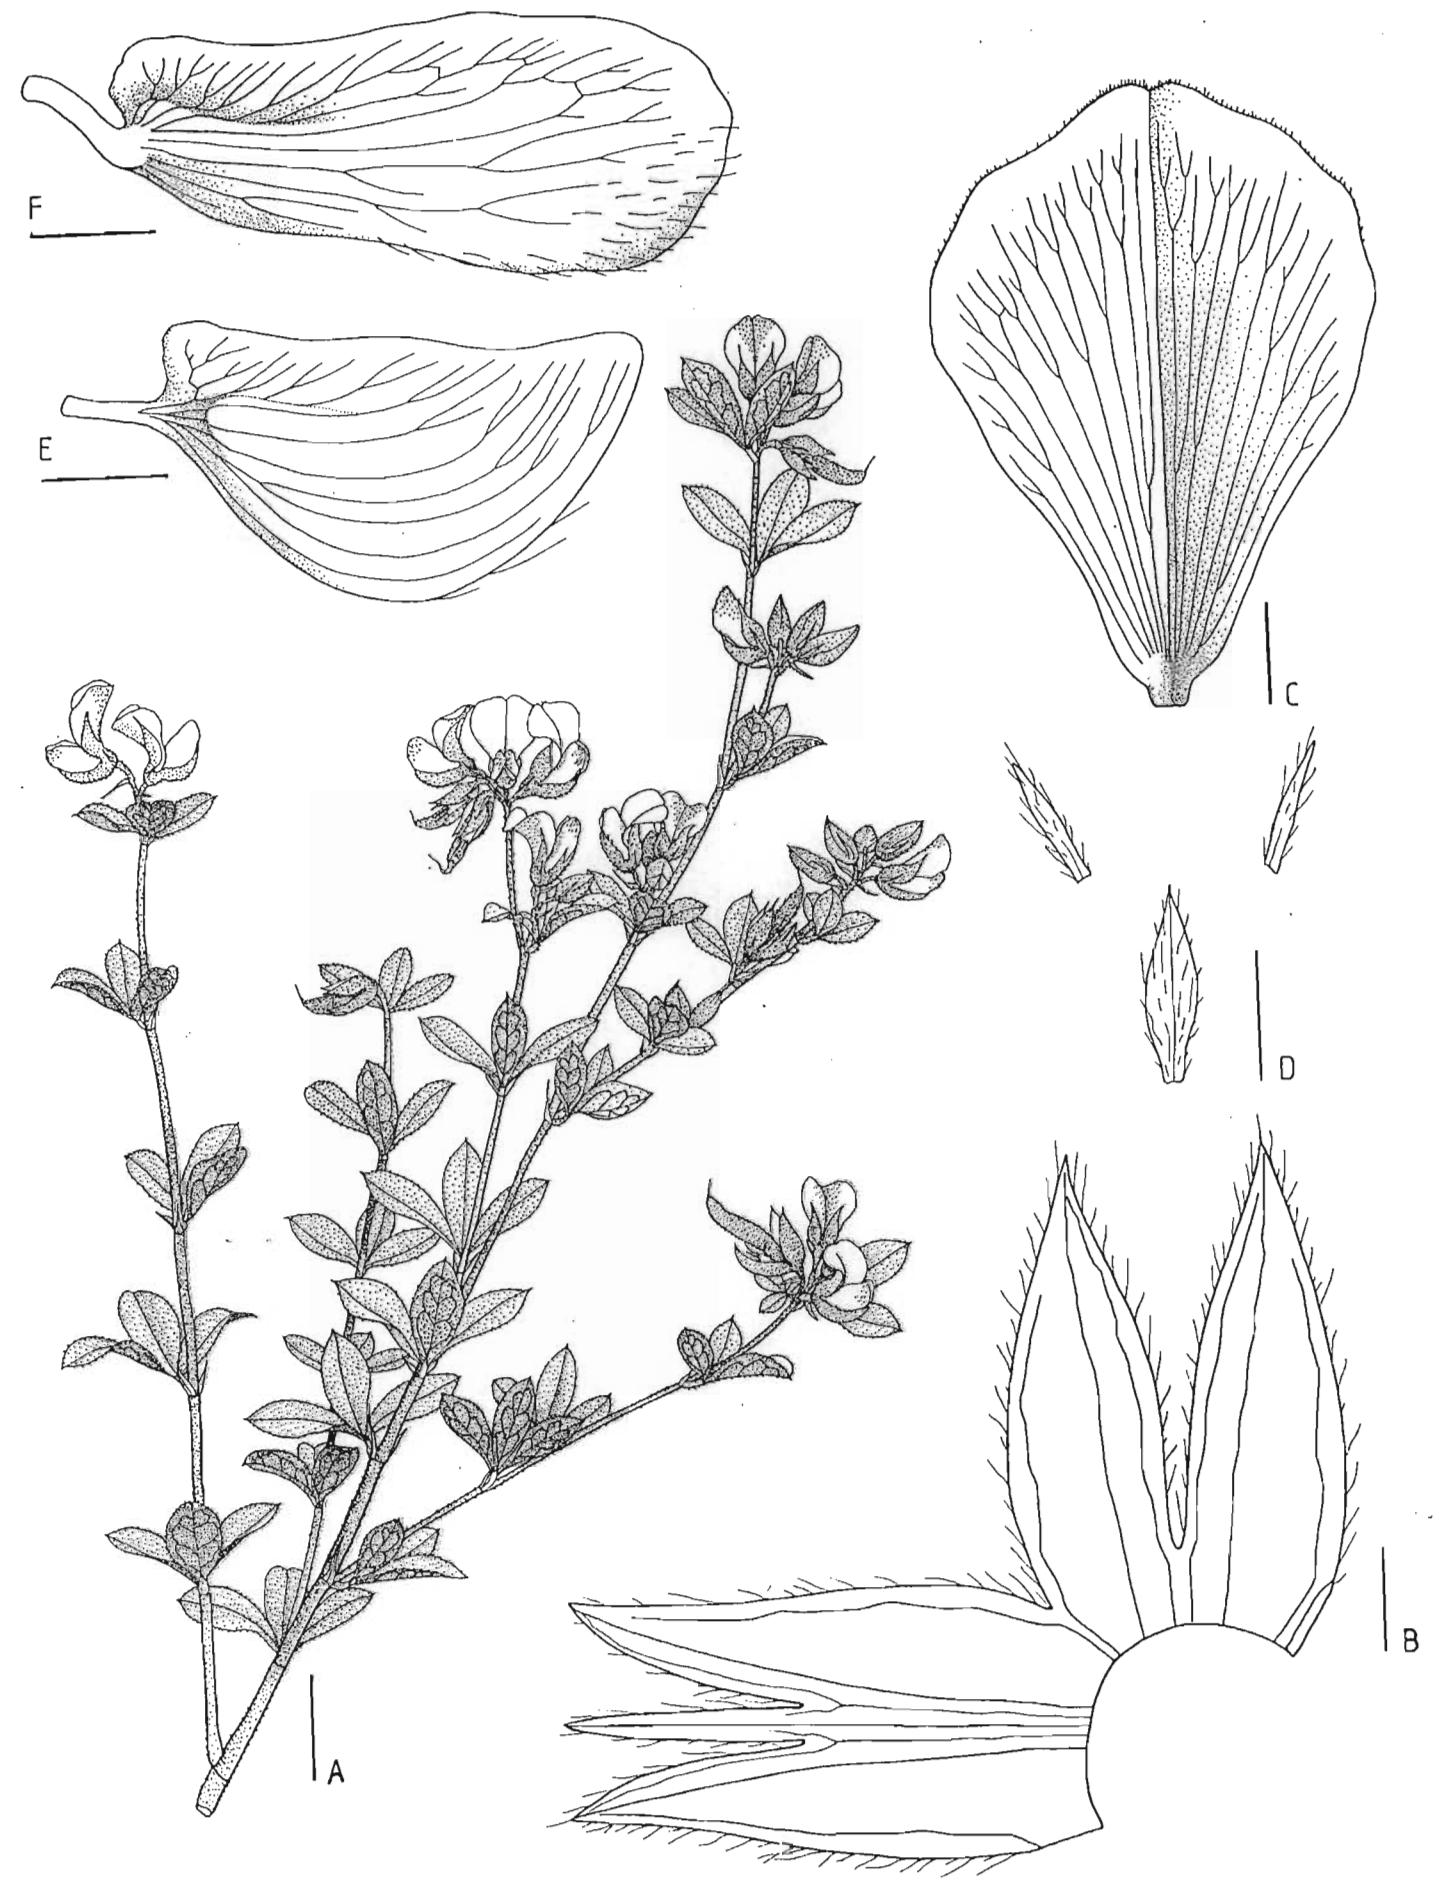

Type species: *A. transvaalense* Schinz.

Suffrutices, erect, usually well branched, with woody stem bases, variously sericeous. *Leaves* variously sericeous; stipules lanceolate to ovate. *Inflorescence* racemose to pseudo-umbellate, terminal or axillary; bracts ovate to lanceolate; bracteoles lanceolate. *Calyx* variously sericeous; sinuses well developed to vestigial. *Corolla* yellow becoming russet with age; standard ovate, obovate or suborbicular, adaxial surface sericeous, base obtuse to cuneate, claw undifferentiated; wings oblong to obovate, sometimes sericeous, sculpturing lunate

or absent; keel cymbiform, abaxial suture sometimes sparsely sericeous. *Stamens* monadelphous, sheath often deeply split adaxially. *Ovary* narrowly oblong. *Fruit* sericeous, sub-torulose or compressed. *Seed* irregular or suborbicular, 1–3 mm in diameter.

5. *Argyrolobium frutescens* Burtt Davy, A manual of the flowering plants and ferns of the Transvaal with Swaziland, South Africa, 393 (1926). Type: eastern Transvaal, Barberton, Rogers 23984 (K!, lecto. selected here; J!, isolecto.).

Suffrutex, up to 1 m tall, erect, well branched, stems sericeous, becoming glabrous. *Leaves* sericeous; leaflets elliptic to obovate, 10–35 (–55) x 4–13 mm, apex acute to rounded, apiculate; petiole 2–5 mm long; stipules lanceolate to ovate, 3–7 x 0.5–2 (–3) mm. *Inflorescence* racemose to pseudo-umbellate, 1–12-flowered, terminal or axillary; peduncle 0–30 mm long, densely sericeous; bracts ovate to lanceolate, 3–5 x 0.5–1.5 mm; bracteoles lanceolate, 2.5–3 x 0.5 mm. *Calyx* fulvous-sericeous; upper lip 10–11 mm long, sinus 7–8 mm deep; lower lip 10–12 mm long, lobes 4–6 mm long, united apically, medial lobe linear. *Corolla* yellow becoming russet with age; standard obovate, 10–12 x 9–11 mm, adaxial surface densely sericeous, base cuneate, claw 1 mm; wings oblong to obovate, 10–11 x 4–4.5 mm, with vestigial, lunate sculpturing in the upper basal and upper central zones, claw 1 mm, apex sericeous; keel narrowly cymbiform, 9–10 x 4–4.5 mm, claw 1 mm, abaxial suture sparsely sericeous. *Stamens*

monadelphous, sheath split above almost to the base. *Ovary* narrowly oblong; 7--8 mm long; style 3.5--4.5 mm long. *Fruit* sericeous, sub-torulose, 30-45 x 5 mm. *Seed* not seen.

This species is limited to serpentine soils around Barberton in North-Eastern Mountain Sourveld and Lowveld Sour Bushveld (Figure 51). It is closely allied to *A. fischeri* of Tropical Africa from which it is distinguished by its short petioles. It occupies similar habitats to *A. fischeri*, usually in scrubby vegetation and often along forest margins.

6. *Argyrolobium transvaalense* Schinz in Bulletin de L'Herbier Boissier 7: 33

Figure 49

Argyrolobium frutescens. A. Flowering branch (bar = 20 mm); B. calyx (bar = 2 mm); C. standard (bar = 2 mm); D. bract & bracteoles (bar = 2 mm); E. keel (bar = 2 mm); F. wing (bar = 2 mm). Voucher: *Edwards* 1116.

(1899); Burtt Davy: 392 (1926). Type: Transvaal, Makapansberge (Streypoort), *Rehmann* 5553 (B†, BM!, lecto. selected here), Houtbosch, *Rehmann* 6264 & 6263 (B†, syn.).

Argyrolobium lancifolium Burtt Davy, A manual of the flowering plants and ferns of the Transvaal with Swaziland, South Africa, 392 (1926), *synon. nov.* Type: eastern Transvaal, Lydenburg, between Pilgrims Rest and Sabie, *Rogers* 18237 (K!, syn.), *Rogers* 14351 (PRE!, syn.), *Rogers* 23225 (BM!, lecto. selected here; J!, PRE!, isolecto.).

Suffrutex, up to 0.7 m tall, erect, well branched, stems sericeous, becoming glabrous. *Leaves* sericeous to sparsely sericeous beneath, glabrescent above; leaflets oblong-obovate to broadly obovate, 20--50(--65) x 10--35 mm, apex rounded, apiculate; petiole 2--4 mm long; stipules lanceolate to ovate, 1--5 x 0.5--1.5 mm. *Inflorescence* racemose, 3--30-flowered, terminal or axillary; peduncle densely sericeous; bracts linear to lanceolate, 2--4 x 0.5 mm; bracteoles lanceolate, 1--3 x 0.5 mm. *Calyx* fulvous-sericeous; upper lip 5--7 mm long, sinus 3--4 mm deep, sometimes incompletely split; lower lip 6--10 mm long, lobes 0.5--2 mm long, medial lobe linear. *Corolla* yellow becoming russet with age; standard broadly ovate to suborbicular, 11--16 x 10--18 mm, adaxial surface sericeous, base obtuse, claw 2.5--3 mm long; wings oblong to obovate, 9--14 x 4--6 mm, with lunate or lunate-lamellate sculpturing in the upper basal and upper central zones, claw 1.5--2 mm long; keel narrowly cymbiform, 8--11 x 4--5 mm, claw

1--2 mm long. *Stamens* monadelphous, sheath split more deeply above. *Ovary* narrowly oblong, 7--13 mm long; style 3 mm long. *Fruit* sericeous, compressed, 40--65 x 4--5 mm. *Seed* irregular, 2.5--3 x 2--3 mm.

A. transvaalense is closely allied to *A. muddii* but is a taller, virgate species with smaller flowers and is widely distributed in the Transvaal. *A. muddii* only occurs in afromontane grassland where it forms many-stemmed clumps seldom exceeding 0.4 m in height. *A. lancifolium* is reduced to synonymy with *A. transvaalense* because variation of leaflet shape, vestiture and flower size is not disjunct.

The species occurs mainly in Sour Bushveld, North-Eastern Mountain Sourveld and Lowveld Sour Bushveld (Figure 51).

7. *Argyrolobium muddii* Dümmer in Kew Bull. 1912: 271 (1912); Burtt Davy: 392 (1926). Type: Transvaal, summit of Mt. MacMac, *Mudd s.n.* (K!, holo.).

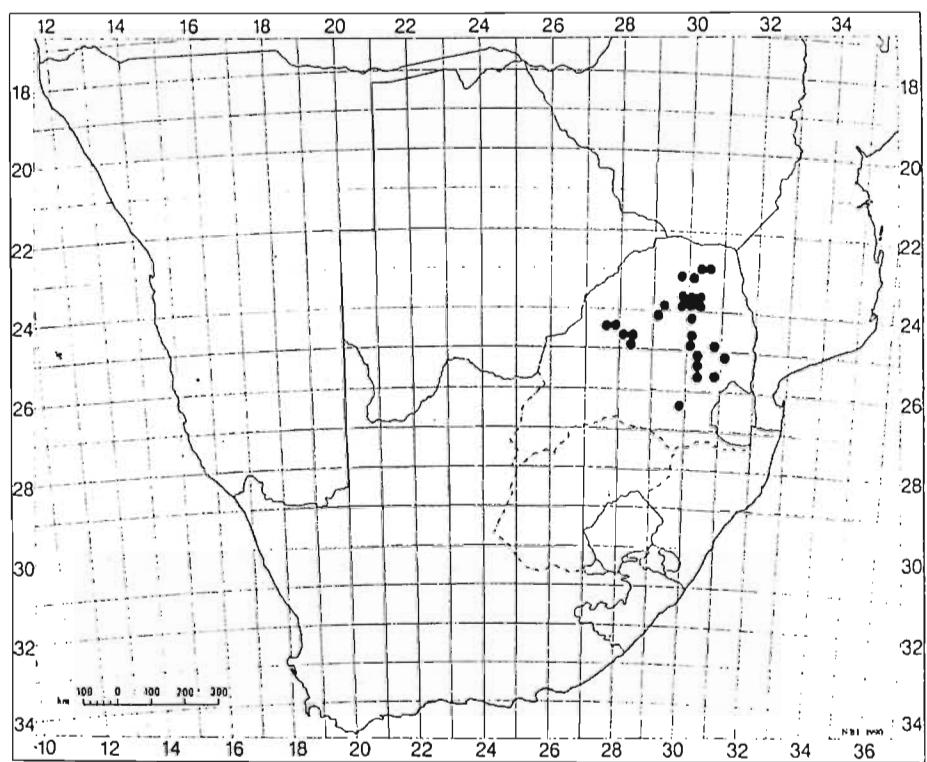

Suffrutex, forming many-stemmed clumps, up to 0.4 x 0.6 m, stems erect, sericeous to villose, becoming glabrous, often flowering precociously. Leaves moderately sericeous to sparsely villose; leaflets broadly obovate, 20--40 x 9--25 mm, apex rounded; petiole 3--9 mm long; stipules lanceolate to ovate, 3--12 x 0.5--3 mm. Inflorescence racemose, 3--17-flowered, terminal; peduncle sericeous; bracts linear-lanceolate to oblanceolate, 4--7 x 1--2 mm; bracteoles linear, 2--4 x 0.5 mm. Calyx fulvous-sericeous; upper lip 12--14 mm long, sinus 10 mm deep,

Figure 50

Argyrolobium transvaalense. A. Flowering branch (bar = 20 mm); B. androecium (bar = 2 mm); C. keel (bar = 2 mm); D. wing (bar = 2 mm); E. standard, abaxial surface (bar = 2 mm); F. calyx with subtending bracts and bracteoles (bar = 2 mm). Voucher: *Edwards* 573.

A.

B.

Figure 51. Recorded distribution of A. *A. frutescens* & B. *A. transvaalense*.

sometimes incompletely split; lower lip 14–17 mm long, lobes 3–5 mm long, medial lobe linear. *Corolla* yellow becoming russet with age; standard broadly ovate to suborbicular, 18–21 x 17–21 mm, adaxial surface sericeous, base obtuse, claw 2 mm long; wings oblong to obovate, 14–17 x 5–6 mm, without sculpturing, claw 2–3 mm long; keel narrowly cymbiform, 13–17 x 5–6 mm, claw 2 mm long. *Stamens* monadelphous, sheath split more deeply above. *Ovary* narrowly oblong; 9–12 mm long; style 4–5 mm long. *Fruit* sericeous, compressed, 50–85 x 6–7 mm. *Seed* shape irregular, 2–3 x 2–3 mm.

This species is occasionally confused with *A. transvaalense*. It is distinguished by its shorter stature and many-stemmed clumps, by the occurrence of considerable vestiture on the adaxial leaflet surfaces, by its prominent petioles and stipules and by its larger flowers. The absence of petal sculpturing is not a reliably diagnostic because the character is unstable within *A. transvaalense*.

A nexus of species exists in the eastern Transvaal including: *A. muddii*, *A. transvaalense*, *A. lancifolium*, *A. frutescens* and *A. megarrhizum*. Of these *A. muddii* bears the largest flowers and occupies one of the narrowest distributional ranges (Figure 54). Its habitat comprises mistbelt grassveld along the escarpment and consequently its distribution is disjunct. The species is common in North-Eastern Mountain Sourveld.

2329 (Pietersburg): Ramothola ("Ramatula"), northern Transvaal, (--DB), *Moss* 951 (BM); Dap Naude Dam, (--DD), *Stirton* 5738 & 5741 (PRE); Haenertsburg, (--DD), *Swierstra s.n.* (PRE); *Sidey* 1295 (PRE); *Rogers* 19024 (J); *Van der Merwe* 52 (PRE). 2330 (Tzaneen): Woodbush Mountains, (--CC), *Moss* 15483 (BM, J); Magoebaskloof, (--CC), *Schweicherdt* 1673 (B). 2429 (Zebediela): Wolkberg, (-BB), *McCallum, Balkwill & Cadman* 3009 (J, NU). 2430 (Pilgrims Rest): Graskop near Natural Bridge, (--DD), *Hilliard & Burtt* 18457 (E, PRE); *Galpin* 14545 (B, BOL); *Germishuizen* 3509 (PRE); *Kluge* 1957 (PRE); *Galpin s.n.* (BOL); *Edwards* 654 (NU). ^u

8. *Argyrolobium wilmsii* Harms in Engl. Jahrb. 26: 283 (1899); Burtt Davy: 393 (1926). Type: eastern Transvaal, near Lydenburg, *Wilms* 257 (K!, lecto. selected here; BM!, E!, G!, isolecto.).

Argyrolobium nitens Burtt Davy: 393 (1926), *synon. nov.* Type: eastern Transvaal, between Pilgrims Rest and Lydenburg, *Rogers* 23111 (BOL!, lecto. selected here; PRE!, isolecto.).

Suffrutex, 0.3–0.9 m tall, prominently branched above, stems velutinous. *Leaves* often deciduous before anthesis; leaflets broadly obovate to oblong-elliptic, 10–55

Figure 52

Argyrolobium muddii. A. Habit (bar = 20 mm); B. calyx (bar = 2 mm); C. androecium (bar = 2 mm); D. standard, abaxial surface (bar = 2 mm); E. keel (bar = 2 mm); F. wing (bar = 2 mm). Voucher: *Edwards* 654.

x 4–36 mm, velutinous, apex rounded occasionally emarginate, apiculate, petiole 2–6 mm long; stipules often caducous, linear-lanceolate, 3–5 x 0.5–1 mm.

Inflorescence 2–20 (–30)-flowered, densely racemose occasionally paniculate, terminal; bracts linear-lanceolate, 4–8 x 0.5–1 mm; bracteoles linear-lanceolate, 2–6 x 0.5 mm. *Calyx* velutinous, upper lip 9–12 mm long, sinus 5–7 mm deep; lower lip 11–13 mm long, lobes 2–3 mm long. *Corolla* yellow; standard suborbicular, 12–14 x 11–15 mm, adaxial surface sparsely sericeous, base obtuse, claw 1–1.5 mm long; wings obovate to oblong, 11–13 x 4–5 mm, sculpturing lunate-lamellate in the upper basal zone, claw 1–1.5 mm long; keel cymbiform, 9–11 x 3–4 mm, often sparsely ciliate along the lower suture, claw 1–2 mm long. *Stamens* monodelphous fused adaxially. *Ovary* 6–7 mm long, densely sericeous; style 4–6 mm long. *Fruit* velutinous, compressed, 40–55 x 5–6 mm. *Seed* red-brown, orbicular or irregular, 3 x 2.5 mm.

Burtt Davy (1926) distinguished *A. nitens* on the basis of its smaller flowers, slender branches and closely appressed pubescens. Our research has shown that the type specimen (*Rogers 23111*) falls well within the range of variation of *A. wilmsii* and *A. nitens* is therefore reduced to synonymy.

A. wilmsii is a distinctive species characterised by its silver leaves and floriferous nature. Some confusion is apparent in the tentative identification of herbarium specimens and this is often due to the inconsistent defoliation of plants before

anthesis. The species is common in Piet Retief Sourveld and North-Eastern Mountain Sourveld (Figure 54).

2329 (Pietersburg): Haenertsberg, (--DD), *Meeuse* 9822 (PRE). 2428 (Nylstroom): Makapaans Valley, (--AA), *Maguire* 918 & 947 (J); *Maguire* 920 (BOL, NBG, PRE). 2429 (Zebediela): Potgietersrus, (--AA), *Rogers* 2384 (PRE); Donkerkloof, Chuniespoort, (--BA), *Vahrmeijer* 2427 (MO, PRE); Ashmole Dales, (--BB), *Pole-Evans s.n.* (PRE). 2430 (Pilgrims Rest): The Downs, (--AA), *Rogers* 20155 (BOL). 2529 (Witbank): Stoffberg, Monsterlus, (--BA), *Obermeyer s.n.* (BOL, NH, PRE). 2530 (Lydenburg): Komati Bridge, (--AA), *Compton* 26044 (NBG); farm Livagershoek, (--AB), *Obermeyer* 196 (PRE); Lydenburg, (--AB), *Wilms* 257 (BM, E, G); *Wilms* 5795 (PRE); *Wilms* 254 (BM); *Edwards* 562 (NU); *Germishuizen* 438 (PRE); *Evans s.n.* (PRE); *Repton* 702 (BOL, NH); *Codd* 538 (PRE); farm De Kuilen, (--AB), *Anderson s.n.* (PRE); Spekboom River, *Young s.n.* (NH); between Origstad & Pilgrims Rest, (--AB), *Rauh & Schlieben* 9651 (PRE); between Lydenburg & Pilgrims Rest, (--AB), *Rogers s.n.* (PRE); *Rogers* 23111 (BOL, PRE); Crocodile River, (--BC), *Schlechter* 3904 (BOL, BR, C, E, G, GRA, NH); Rosehaugh, (--BD), *Mogg* 13961 (PRE); Lowveld Botanic Gardens, Nelspruit, (--BD), *Buitendag* 167 (NBG); Nelspruit, (--BD), *Prosser* 1288 (NBG); *Prosser* 1488 (J, NBG); *Van Jaarsveld* 34 (NBG, PRE); *Britten* 4796 (PRE). 2531 (Komatipoort): 8 km from Lydenburg on rd. to Origstad, (-AB), *Schrile* 638 (NH); White River, (--AC), *Galpin* 14557 (BOL, PRE);

8. *Argyrolobium megarrhizum* H. Bol. in Journ. Linn. Soc. 24: 175 (1887); Burtt Davy: 392 (1926). Type: Transvaal, around Pretoria, *MacLea s.n.* (BOL!, lecto. selected here; BM!, K!, SAM!, isolecto.).

Suffrutex, up to 0.6 m tall, erect, well branched, stems sericeous, becoming glabrous. *Leaves* sericeous to sparsely sericeous beneath, glabrescent above; leaflets linear-lanceolate to oblong-obovate, 10--30 x 2--5 mm, apex rounded, apiculate; petiole 3--7 mm long; stipules linear to subulate or absent. *Inflorescence* racemose, 3--6-flowered, terminal; peduncle densely sericeous; bracts linear 3-4 x 0.5 mm; bracteoles linear to subulate, 2--3 x 0.5 mm. *Calyx* fulvous-sericeous; upper lip 6--8 mm long, sinus vestigial; lower lip 7--10 mm long, lobes vestigial. *Corolla* yellow; standard broadly ovate to suborbicular, 15--18 x 13--17 mm, adaxial surface sparsely sericeous apically, base obtuse, claw 2.5--3 mm long; wings oblong to obovate, 11--14 x 5--6 mm, with prominent lunate-lamellate

Figure 53.

Argyrolobium wilmsii. A. Flowering branch (bar = 20 mm); B. calyx (bar = 2 mm); C. keel (bar = 2 mm); D. wing (bar = 2 mm); E. androecium (bar = 2 mm); F. standard, abaxial surface (bar = 2 mm); G. standard, lateral view (bar = 2 mm). Voucher: *Edwards* 562.

sculpturing in the upper basal and upper central zones, claw 1.5--2 mm long; keel narrowly cymbiform, 11--13 x 4--6 mm, claw 2--3 mm long. *Stamens* monadelphous, sheath split deeply above. *Ovary* narrowly oblong; ovary 8--9 mm long; style 3--5 mm long. *Fruit* sericeous, compressed, 40--100 x 4--5 mm. *Seed* shape irregular, 3--5 x 3--4 mm.

Argyrolobium megarrhizum is closely allied to *A. transvaalense* and *A. muddii* but its calyx lobes are vestigial. Other characters which distinguish *A. megarrhizum* from *A. transvaalense* are its prominently petiolate leaves and its clumping habit. It is distinguished from *A. muddii* by its narrow leaflets and its prominent wing sculpturing.

A. megarrhizum occurs in Mixed Bushveld and Sourish Mixed Bushveld around Pretoria (Figure 54).

2528 (Pretoria): Rust de Winter Dam, (--AB), *Pole Evans s.n.* (PRE); Pretoria, Magaliesberg, (--CA), *McLea 161* (SAM); *McLea 163* (BM); *McLea 5635* (BM, BOL, SAM); between Pretoria & Witnek, Cullinan, (--CB), *Grobbelaar 2515* (PRE); Trichardspoort, Rhenosterkop, (--DA), *Obermeyer s.n.* (GRA, PRE); Bronkhorstspruit on Rd. to Rust de Winter, (--DA), *Clarke 411* (MO, PRE); Rd. to army radar tower, Bronkhorstspruit to Verena, (--DB), *Grobbelaar 1667* (MO).

2529 (Witbank): between Verena & Bronkhorstspruit, (--AB), *Mauve & Venter*

9. *Argyrolobium longifolium* (Meisn.) Walp. Repert. Bot. Syst. 2: 844 (1843); Harv.: 69 (1862); Edwards: 42 (1994). Type: Natal, summit of Table Mountain, *Krauss* 214 (TCD!, lecto. selected here; G!, K!, MO!, PRE!, W!, isolecto.).

Chasmone longifolia Meisn.: 74 (1843). Type: as above.

Argyrolobium natalense Dümmer: 272 (1912). Type: Natal, *Wood* 861 (K!, lecto. selected here; BOL!, K!, PRE!, SAM!, isolecto.).

Virgate suffrutex, up to 1.5 m tall, erect; stems sparingly branched below, well branched above, sparsely sericeous, becoming glabrous; lignotuber well developed. Leaves glabrous adaxially, sparsely sericeous abaxially; dimorphic in mature plants, upper leaflets oblanceolate to linear, conduplicate, lower leaflets broadly oblanceolate to elliptic, 30–70 x 4–16 mm, caducous, apex acute or rounded, apiculate; seedling leaflets suborbicular, 10–30 x 8–25 mm; petiole 15–30 mm long; stipules sericeous abaxially, lanceolate in mature plants, minute in seedlings. Inflorescence racemose, subsecund, up to 20-flowered, terminal, often subtended by axillary inflorescences; bracts linear, up to 6 x 1 mm, bracteoles

minute. *Calyx* sericeous, deeply bilabiate; upper lip incipiently bidentate, 9–12 mm long, lower lip 10–14 mm long. *Corolla* lemon yellow, becoming black in dried specimens; standard 10–13 x 10–12 mm, broadly suborbicular, adaxial surface sparsely sericeous, base canaliculate, claw 2–3 mm long; wings oblong to obovate, 10–12 x 3–4.5 mm, with lunate-lamellate sculpturing in the basal and upper central zones, claw vertical, 2–3 mm long; keel acutely cymbiform, 7–9 x 3–4 mm, claw vertical, 2.5–3 mm long. *Stamens* monadelphous, sheath split adaxially. *Ovary* narrowly oblong, 9–10 mm long, style 3–4 mm long. *Fruit* linear, up to 60 x 4 mm, sparsely sericeous, compressed between the seeds. *Seed* red-brown, 2–3 mm in diameter, slightly compressed.

Meisner's original description of this species overlooked the occurrence of dimorphic anthers, often with flattening of the five short filaments. This, together with habit and unusual inrolling of the standard base, indicates a close alliance between *A. baptisioides* Eckl. & Zeyh. and *A. longifolium*. On drying these species turn black.

Dümmer's description of *A. natalense* has led to confusion. His species concept is based on the "glabrescent character and more slender racemes" of *A. natalense*. The current investigation has found no evidence to support the recognition of two species. Raceme stature depends on the part of the plant from which the collection was made, axillary racemes are frequently slender while terminal racemes tend to

be robust. Vestiture in this species is also variable, young growth is invariably hairy but mature growth tends to be glabrescent. For these reasons *A. natalense* was reduced to synonymy.²³

Examination of herbarium material shows that *A. longifolium* and *A. tuberosum* are frequently confused. Live material is easily distinguished on the basis of flower colour and habit. The combination of russet and yellow in fresh flowers of *A. tuberosum* (discussed under *A. pseudotuberosum*) is unique within the genus. In addition *A. tuberosum* is a slender poorly branched herb seldom exceeding 500 mm in height. Unfortunately herbarium specimens of *A. longifolium* are often derived from simple axillary branches which superficially resemble whole plants of *A. tuberosum*.

A. longifolium is usually encountered in Ngongoni Veld, Highland Sourveld and Dohne Sourveld (Figure 105).

2930 (Pietermaritzburg): Dargle, (--CA), Wood 11620 (BOL); between Camperdown and Maritzburg, (--DA), Gerrard & Mc Ken 2127 (TCD); Wood 11079 (NU, PRE); Edwards 353, 402 & 827 (NU); Tafelberg, (--DA), Krauss

10a. *Argyrolobium speciosum* Eckl. & Zeyh. subsp. *speciosum*, Enum. Pl. Afr. Austr. 2: 187 (1836); Walp.: 506 (1839); Walp.: 630 (1843); Harv.: 68 (1862). Type: Winterberg near Phillipstown, *Ecklon & Zeyher* 1320 (K!, lecto. selected here; C!, G!, MO!, NY!, O!, P!, S!, TCD!, isolecto.).

Chasmone diversifolia E. Mey.: 71 (1836). Types: in grassland, Katberg 3000–3500', *Drège s.n.* (P!, lecto. selected here; G!, PRE!, S!, TCD!, isolecto.); between Zandplaat & Komga 2400', *Drège s.n.* (P!, syn.). Incorrectly as *Chasmone heterophylla* in Harv.: 68 (1862).

Herb 0.15–0.3 m tall, erect, sparingly branched; stems annual, cylindrical in section, pilose, becoming glabrous. Leaves glaucous, slightly fleshy, glabrescent

but often abaxially sericeous when young; leaflets narrowly obovate or elliptical to broadly obovate or elliptical, 30--70 x 15--20 mm, apex rounded or acute; petioles 5--26 mm long, canaliculate; stipules often abaxially sericeous at first, trapezoid, base broadly cuneate, apex acute. *Inflorescence* racemose, 2--25-flowered, up to 270 mm tall, terminal, rarely becoming leaf-opposed; peduncle 50--220 mm, glabrescent, sericeous or pilose; bracts linear, 6--15 x 0.75--1.25 mm, bracteoles setaceous, 2--3 x 0.5 mm. *Calyx* sparsely to densely sericeous, lateral sinuses 7--10 mm; upper lip 8--12 mm long, lobes acute, 3--9 x 1.7--2 mm; lower lip 8--13 mm long, lobes acute, 1.5--5 x 0.75--2 mm. *Corolla* bright to mustard yellow, standard veins red; standard lamina suborbicular, 7--13 x (6--)11--13 mm, adaxial surface sparsely sericeous centrally, claw 2.5--4 mm long; wing laminae obovate to slightly cymbiform, 8--11 x 3--6 mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw 2--3.5 mm long. *Fruit* linear, compressed, erect, sparsely sericeous, 60--85 mm long. *Seed* irregular to suborbicular, compressed, 2--3 mm, sometimes recalcitrant, testa light brown, hilum slightly raised.

The variation in leaf dimensions within this species is remarkable and some correlation with inflorescence structure and provenance exists. Two subspecies are recognised to accommodate this variation. Plants of the northern subspecies are robust with large leaflets and reduced petioles. The type subspecies, from the eastern Cape is smaller with short, lower internodes and thus the leaves are in basal clusters. The leaflets are both shorter and narrower than their northern

relatives. A correlated trend occurs in the peduncle development which is accentuated in the typical subspecies, allowing the flowers to be held above the surrounding vegetation despite the reduced vegetative stature of the plants (Figure 56). A stronger tendency towards leaf dimorphism is also apparent in southern subspecies, with broad lower leaflets and narrow upper leaflets.

The typical subspecies occurs mainly in Highland and Dohne Sourveld.

Without precise locality: *Barber s.n.* (TCD). 3226 (Fort Beaufort): Winterberg not far from Phillipstown, (--AC), *Ecklon & Zeyher* 1320 (C, G, MO, NY, O, P, S, SAM, TCD); *Barber* 46 (TCD); Kouga Mountains, (--CA), *Fitchett* 5008 (PRE); Katberg, (--DA), *Drège s.n.* (BM, G, P, PRE, S, SAM, TCD); *Young* 15363 (J); *Ecklon & Zeyher s.n.* (SAM); *Hutton s.n.* (TCD, UPS); *Hutchinson* 1676 (BM, BOL, PRE); *Sole* 380 (PRE); *Dyer* 1788 (GRA); *Garabestian s.n.* (PRE, SAM); Seymour, (--DB), *Giffen s.n.* (PRE); *Scully* 595 (BM, BOL, G, UPS); Gaika's Kop, (--DB), *Phillipson & Hutchings* 50 (KEI, MO, PRE, UFH). 3227 (Stutterheim): Happy Valley, Cathcart, (--AC), *Barker* 900 (BOL, NBG); Fort Cunynghame, (--AD), *Schonland* 89 (GRA); Keiskama Hoek, Cato Forest Reserve, (--CA), *Story* 3337 (PRE); Evelyn Valley, (--CB), *Taylor* 4226 (NBG); Pirie Forest, King Williams Town, (--CD), *Flanagan* 2198 (GRA, MO, PRE, SAM); *Rattray* 354 (BOL); Muden Dam, King Williams Town, (--CD), *Wehmeyer* 17 (PRE); Pirie, (--CD), *Sim* 19465 (NH); between Zandplaat &

10b. *Argyrolobium speciosum* Eckl. & Zeyh. subsp. *macrophyllum* T.J. Edwards subsp. nov. differt a subspecie *specioso* foliis magnis, habitu robusto, infloresceniis multifloris.

Typus: eastern Transvaal, Barberton, *Thorncroft 19158* (PRE!, holo.; BOL!, C!, GRA!, J!, M!, SAM!, UPS!, iso.).

Herbaceous suffrutex, 0.3–0.75 m tall, erect, sparingly branched; stems annual, triangular in section, pilose, becoming glabrous. *Leaves* glaucous, slightly fleshy, glabrescent but often abaxially sericeous when young; leaflets narrowly obovate or elliptical to broadly obovate or elliptical, 50–170 x 20–80 mm, apex rounded or acute; petioles 15–40 mm long, canaliculate; stipules often abaxially sericeous at first, trapezoid, base broadly cuneate, apex acute. *Inflorescence* racemose, 20–62-flowered, up to 400 mm tall, terminal, rarely becoming leaf-opposed; peduncle 10–100 mm, glabrescent, sericeous or pilose; bracts linear, 6–15 x 0.75–1.25 mm, bracteoles setaceous, 2–3 x 0.5 mm. *Calyx* sparsely to densely sericeous, lateral sinuses 7–10 mm; upper lip 8–12 mm long, lobes acute, 3–9 x 1.7–2 mm; lower lip 8–13 mm long, lobes acute, 1.5–5 x 0.75–2 mm. *Corolla* bright to mustard yellow, standard veins red; standard lamina suborbicular, 7–13 x (6–)11–13 mm, adaxial surface sparsely sericeous centrally, claw 2.5–4 mm long; wing

laminae obovate to slightly cymbiform, 8–11 x 3–6 mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw 2–3.5 mm long. *Fruit* linear, compressed, erect, sparsely sericeous, 60–85 mm long. *Seed* irregular to suborbicular, compressed, 2–3 mm, sometimes recalcitrant, testa light brown, hilum slightly raised.

Diagnostic aspects are discussed under the typical subspecies. *A. speciosum* ssp. *macrophyllum* occurs commonly in Highland Sourveld, Dohne Sourveld and Ngongoni Veld (Figure 105).²⁴

11. **Argyrolobium baptisioides** (E. Mey.) Walp. in Linnaea 13: 506 (1839);

Walp.: 630 (1843); Harv.: 69 (1862). Type: Katberg, in grassland, 3500--4000', *Drège s.n.* (P!, lecto. selected here; BM!, K!, G!, MO!, OXF!, S!, TCD!, isolecto.).

Chasmone baptisioides E. Mey.: 71 (1836).

Argyrolobium sandersonii Harv.: 594 (1862), *synon. nov.*; Wood: 228 (1902). Type: Natal, flats between Field's and Botha's Hills, *J. Sanderson* 99 (TCD!, lecto. selected here; K!, PRE!, isolecto.).

Argyrolobium sutherlandii Harv.: 594 (1862), *synon. nov.* Type: Natal, near Pietermaritzburg, 2--3000', *Dr. Sutherland s.n.* (TCD!, lecto.; iso. K!, isolecto.).

Argyrolobium speciosum Eckl. & Zeyh. var. *glaberrimum* Harv.: 594 (1862), *synon. nov.* Type: Kreili's Country, *H. Bowker* 280 (TCD!, lecto. selected here).

Argyrolobium comanthum Vogel nom. non rite public. mss. in Hb. Reg. Berol.

Suffrutex, up to 0.7 m tall, erect; stems well branched below, annual, glabrous to densely pilose; lignotuber well developed. Leaves glabrous adaxially, sparsely sericeous to pilose abaxially; oblanceolate, elliptic or broadly obovate, 28--45 (--) 90) x 5--20 (--) 40) mm, apex acute or rounded, apiculate; petiole 3--8 (--) 11) mm long, canaliculate; stipules sericeous abaxially, lanceolate to trapezoid, 6--25 x 2--5 mm, base broadly cuneate, apex acute, commonly the basal leaves are reduced

to amplexicaule stipules. *Inflorescence* racemose, erect, 5–80-flowered, terminal, often subtended by axillary inflorescences; bracts elliptic to lanceolate, up to 3–14 x 0.5–2 mm, bracteoles setaceous to elliptic, 2–10 x 0.3–2 mm. Calyx sericeous, lateral sinuses 1–3 mm; upper lip 6–10 (–12) mm long, lobes acute, 2–3 mm; lower lip 8–15 mm long, lobes acute, 1–3 mm long. *Corolla* bright to mustard yellow, becoming black in dried specimens; standard 10–13 x 10–12 mm, obovate, adaxial surface sparsely sericeous, base cuneate, perpendicular to lamina, claw 2–5 mm long; wings obovate to cymbiform, 8–15 x 3.5–5 mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw vertical, 1.5–3.5 mm long; keel acutely cymbiform, 7–9 x 3–4 mm, claw 2.5–3 mm long. *Stamens* monadelphous, sheath split adaxially. *Ovary* oblong 5–7 mm long, style 3–4 mm long. *Fruit* linear, compressed, erect, (30–) 40–60 (–80) x 4–5.5 mm, sparsely sericeous. *Seed* 2–3 mm in diameter, slightly compressed.

The profusion of synonyms listed under this species is due to the variability associated with its habit, indumentum and leaf shape. Extensive field work reveals that populations often include broad-leaved, glabrescent and narrow-leaved, pilose individuals. In populations of the eastern Cape the narrow-leaved, pilose forms predominate. Flowering of the morphs is simultaneous and considerable independent floral variation exists, especially with reference to the width of the standard. Occasional specimens (*Flanagan 569 & Scully 135*) display peculiar inflorescence structure where the terminal racemes resume vegetative growth at their apices.

Around Camperdown mixed populations of *A. baptisioides* and *A. longifolium* occur and here putative hybrids have been recorded (*Edwards* 586). The contracted flowering period of *A. baptisioides* begins in early spring and only late flowering individuals hybridise with *A. longifolium* which flowers throughout summer. *A. baptisioides* inhabits sourveld areas where grass cover is sparse while *A. longifolium* often occurs where grass cover is dense. Both occur in Ngongoni Veld, Highland Sourveld and Dohne Sourveld (Figure 107).

Sectio 4. *Polyphyllum* T.J. Edwards sect. nov. Fructices, inflorescentia racemosa vel pseudoumbellata, floribus monomorphis.

The species of this section are woody shrubs with monomorphic flowers. The section is limited to Macchia and False Macchia in the eastern Cape.

Type species: *A. polyphyllum* Eckl. & Zeyh.

Shrubs, erect, well branched, stems sericeous, becoming glabrous. *Leaves* variously sericeous; leaflets obovate to lanceolate, apex rounded, emarginate or recurvo-mucronate; stipules setaceous to subulate. *Inflorescence* racemose to pseudo-umbellate, terminal often becoming leaf-opposed; pedunculate; bracts subulate to lanceolate; bracteoles lanceolate to vestigial. *Calyx* sericeous; upper lobes sometimes connate; lower lobes usually connate. *Corolla* yellow becoming russet with age; standard orbicular, adaxial surface sericeous medially, base subcordate; wings oblong to obovate, with lunate-lamellate sculpturing in the upper basal and upper central zones; keel cymbiform. *Stamens* monadelphous, sheath sometimes split above, never to the base. *Ovary* narrowly oblong; style glabrous. *Fruit* sericeous, compressed.

12. **Argyrolobium trifoliatum** (Thunb.) Druce in Rep. Bot. Exch. Cl. Brit. Isles, 1916: 605 (1917).

Galega trifoliata Thunb.: 600 (1823). Type: South Africa, Cape Province, *Thunberg s.n. sub. THUNB-UPS 17401* (UPS!, syn.) & *17402* (UPS!, lecto. selected here).

Argyrolobium sericeum (E. Mey.) Eckl. & Zeyh.: 184 (1836); Benth.: 342 (1844); Harv.: 70 (1862). Type: eastern Cape, Uitenhage, 'Vanstadensriverberge', *Ecklon & Zeyher 1304* (P!, lecto. selected here; G!, GRA!, O!, TCD!, isolecto.).

Dichilus sericeus E. Mey. non Spreng. f.: 154 (1832), *nom. illegit.*

Gamochilum sericeum (E. Mey.) Walp.: 510 (1839), *non Galega sericea* Thunb. *et non Ononis sericea* Thunb.

Chasmone holosericea E. Mey.: 72 (1836), *nom. illegit.* Meisn.: 76 (1843). Type: eastern Cape, Kromrivier, *Drège s.n.* (K!, lecto. selected here; G!, MO!, P!, PRE!, S!, isolecto.); Van Stadensberg, *Drège s.n.* (G!, P!, S!, isosyn.).

Chasmone obcordata E. Mey.: 72 (1836). Type: Uitenhage, *Drège s.n.* (K!, lecto. selected here).

Gamochilum obcordatum (E. Mey.) Walp.: 510 (1839). Type as above.

Argyrolobium obcordatum (E. Mey.) Steud.: 130 (1841). Type as above.

Suffrutex, up to 1 m tall, erect, well branched, lower stems often villose, upper stems sericeous, becoming glabrous. Leaves slightly dimorphic, lower leaves

sparsely villose above, abaxial surface densely villose, upper leaves adaxial surface glabrous abaxial surface densely sericeous; leaflets obovate to obcordate, 10--24 x 8--20 mm, apex rounded, emarginate or recurvo-mucronate; petiole 3--10 mm long; stipules setaceous to narrowly lanceolate, 1--8 x 0.5--1(--2) mm.

Inflorescence racemose to pseudo-umbellate, 3--12-flowered, terminal sometimes becoming leaf-opposed; peduncle sericeous; bracts subulate to lanceolate, 1--4 x 0.5--1 mm; bracteoles slightly smaller, lanceolate to setaceous. *Calyx* sericeous; upper lip 8--10 mm long, sinus vestigial; lower lip 10--12 mm long, lobes usually connate. *Corolla* yellow becoming russet; standard orbicular, 13--16 x 11--15 mm, adaxial surface sericeous medially, base obtuse, claw 1--3 mm long; wings oblong to obovate, 11--13 x 4--6 mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw 2--3 mm; keel cymbiform, 10--12 x 4--5 mm, claw 3 mm long. *Stamens* monadelphous, sheath split above almost to the base. *Ovary* narrowly oblong, 7--9 mm long; style 3--4 mm long. *Fruit* sericeous, compressed, 40--55 x 5 mm. *Seed* dark brown, suborbicular, 2--2.5 mm in diameter.

A. incanum is the closest ally and diagnostic differences are discussed under that species, both occur in False Macchia (Figures 52 & 54). *A. trifoliatum* also shows a strong resemblance to *A. polyphyllum* both have rod-like primary stems and dimorphic leaves, although this character is more strongly developed in the latter.

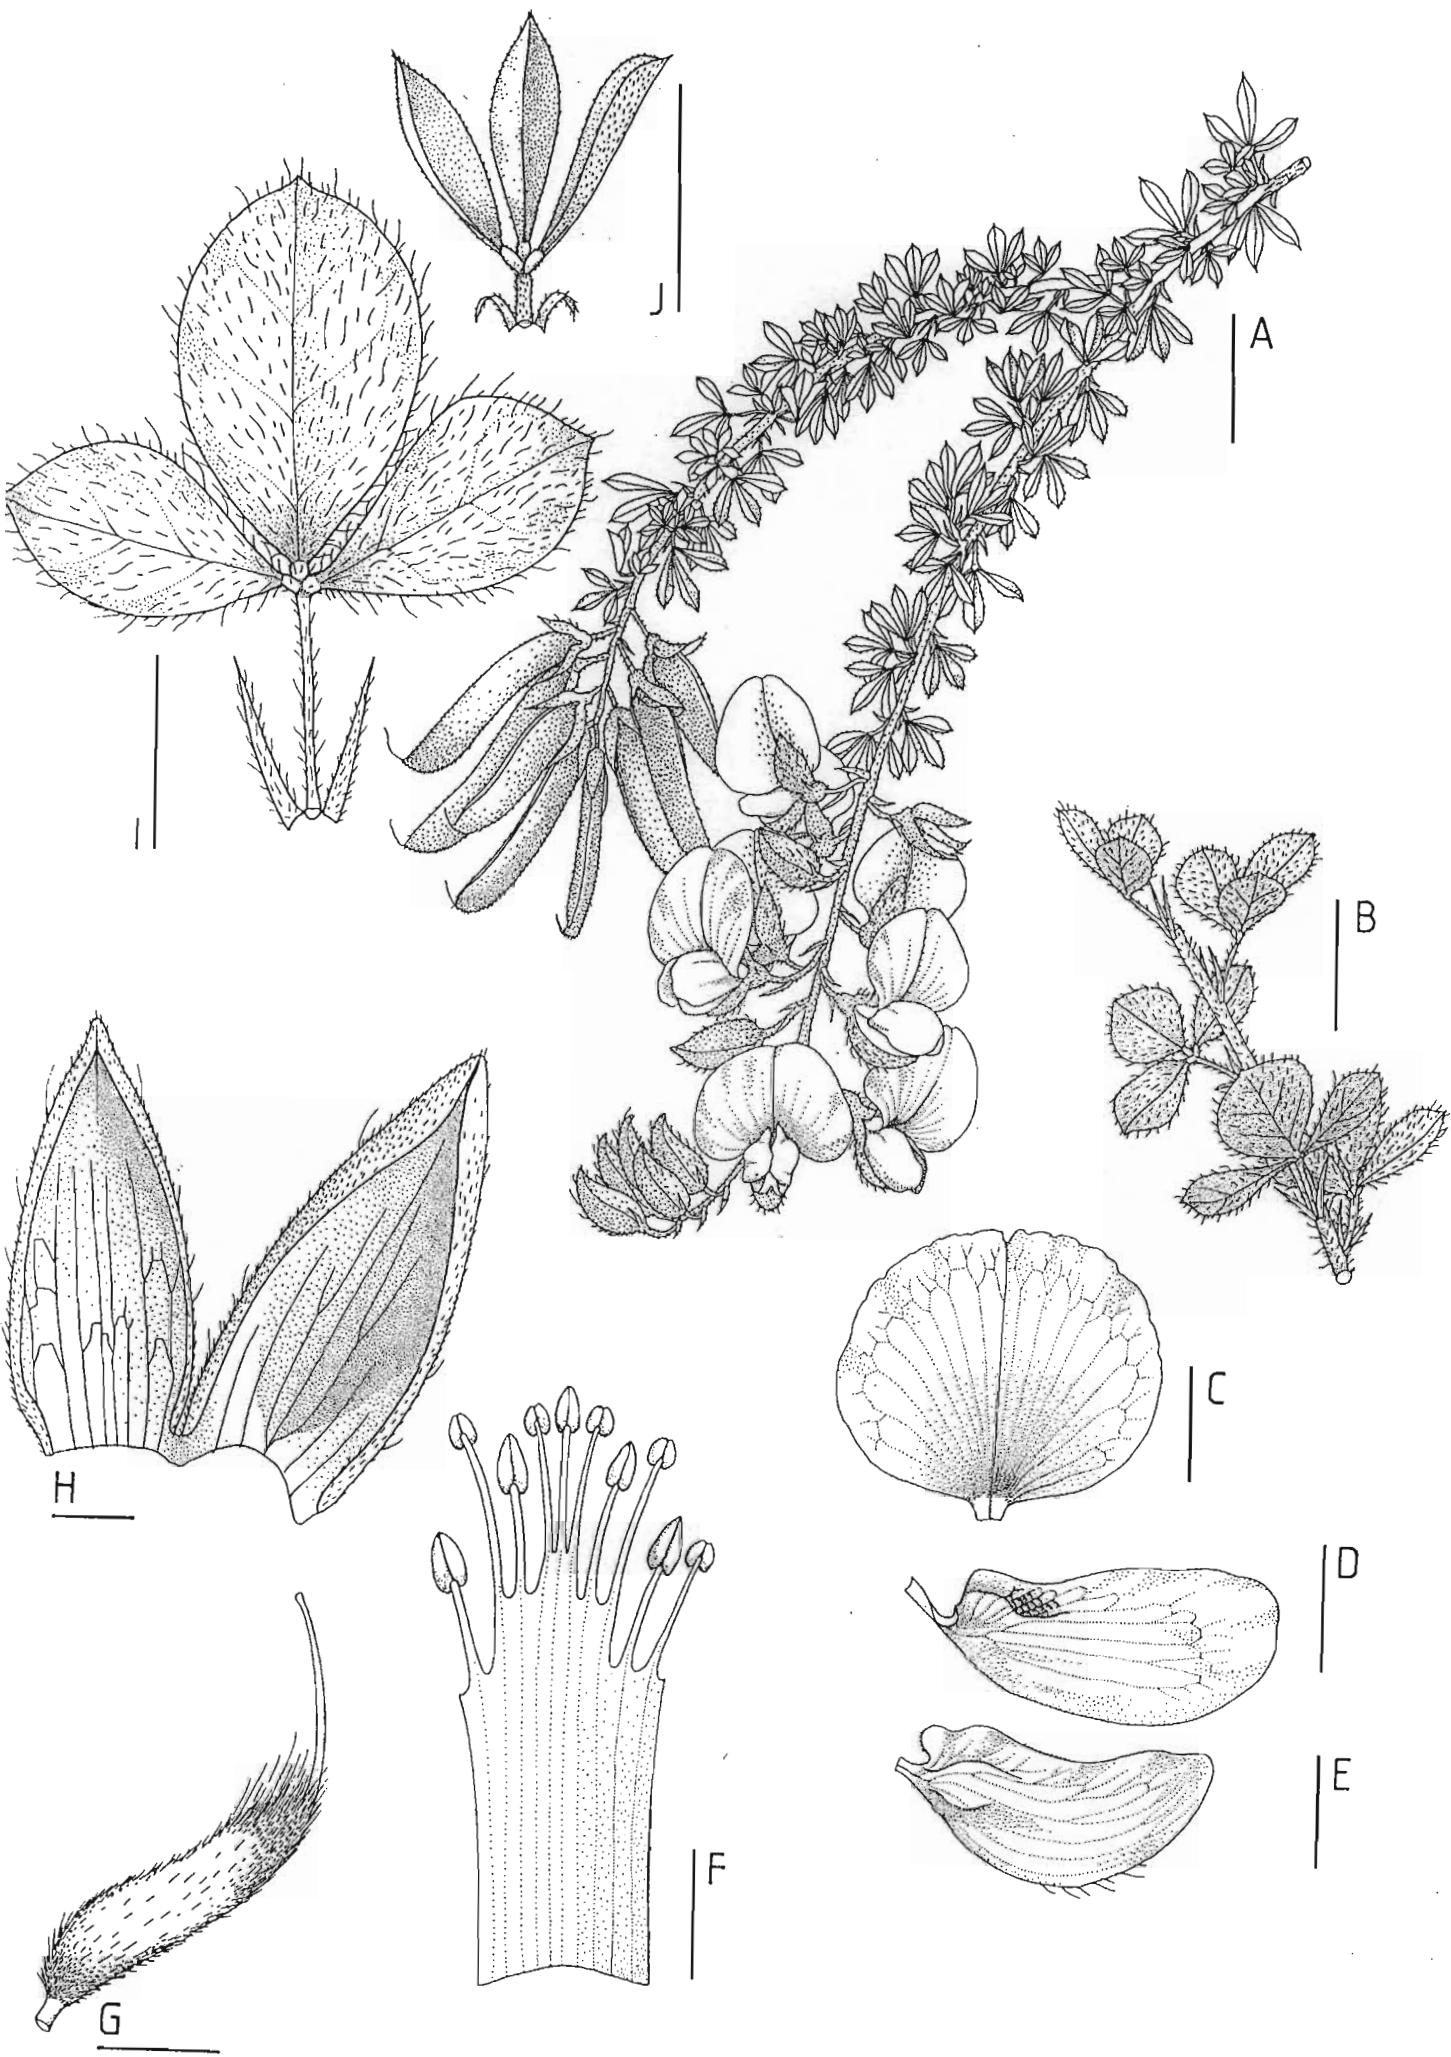

Some confusion existed over the identity of *Galega trifoliata* Thunb. which is the basionym for this name change. Thunberg described the androecium as diadelphous which does not conform with this species however the types have been seen and they undoubtedly belong to this taxon.

Without precise locality: *Drège s.n.* (O); *Masson s.n.* (BM); *Zeyher 1828* (P); *Zeyher 2800* (PRE). 3324 (Steyterville): Assegai Bosch, Humansdorp, (--CD), *Rogers 2831* (BOL, GRA, SAM, PRE); *Fourcade 5366* (BOL, STE); Thornhill on coastal rd. to Humansdorp, (--DD), *Story 2411* (UPS); Hankey Hills, (--DD), *Barker 7848* (NBG, STE). 3325 (Port Elizabeth): Van Stadensberg, (--CC), *Drège s.n.* (G, P, S); *Ecklon 323* (BM, E, GRA, O, P, TCD); *Ecklon & Zeyher 1304* (G, GRA, O, P, S, SAM); *Bolus 1521* (BOL); Otterford, (--CC), *Fourcade 3670* (STE); Longmore Forest Reserve, (--CC), *Dahlstrand 696* (GRA, MO); *MacOwan 1031* (BM); *Urton 44* (GRA); *MacOwan s.n.* (GRA); *Stirton & Zantovska 11600* (STE); *Stirton & Zantovska 11607* (STE); *Dix 112* (BOL, GRA); *Long 67* (STE); Uitenhage, Islandsrivier, (--CD), *Zeyher 2303* (P); Uitenhage, (--DA), *Zeyher s.n.* (E); Bosjesmansrivier, Addo, (--DA), *Zeyher 1311* (P); Port Elizabeth, (--DC), *Archibald & Britten s.n.* (GRA). 3423 (Knysna): Plettenberg Bay, (--AB), *Bowie s.n.* (BM). 3424 (Humansdorp): Humansdorp, (--AB), *Thode s.n.* (NH); *Wells 2951* (GRA); Kromrivier, (--BA), *Drège s.n.* (G, MO, P, S); *Fourcade 2603* (BOL).

13. *Argyrolobium polyphyllum* Eckl. & Zeyh., Enum. Pl. Afr. Austr. 2: 184 (1836); Walp.: 506 (1839); Walp.: 631 (1843); Benth.: 342 (1844); Harv.: 69 (1862). Type: eastern Cape, Chumi and Winterberg, *Ecklon & Zeyher s.n.* (SAM!, lecto. selected here; C!, G!, K!, MO!, O!, P!, isolecto.).

Chasmone cuneifolia E. Mey.: 71 (1836). Type: eastern Cape, Katberg, *Drège s.n.* (G!, lecto. selected here; K!, P!, PRE!, S!, isolecto.).

Shrub, 0.75--2 m tall, prominently branched above, stems sericeous. *Leaves* dimorphic; juvenile and primary leaflets often caducous, narrowly to broadly obovate, 17--45 x 7--20 mm, glabrescent, sparsely sericeous or sparsely pilose, apex rounded, apiculate, petiole 8--20 mm long; stipules falcate to lanceolate, 3--8 x 1--1.5 mm; upper leaflets narrowly obovate to elliptic, 5--9(--17) x 2--4 mm, adaxially glabrous to sparsely sericeous, apex rounded to acute, apiculate, petiole 2--6 mm long; stipules subulate to setaceous, 2--7 x 0.25--1 mm. *Inflorescence* 5--20 (--25)-flowered, densely racemose, terminal; bracts linear-lanceolate, 3--8 x 0.25--1 mm; bracteoles linear lanceolate, 2--5 x 0.5--1 mm. *Calyx* sericeous, upper lip 7.5--10 mm long, sinus 5--7 mm deep, lobes often fused; lower lip 9--12 mm long, lobes 0--1.5 mm long. *Corolla* yellow; standard suborbicular, 11--15 x 10--17 mm, adaxial surface sparsely sericeous, base obtuse, claw 1--1.5 mm long; wings obovate to oblong, 9--14 x 4--7 mm, sculpturing lunate-lamellate in the upper basal zone, claw 0.75--1.5 mm long; keel cymbiform, 5--8 x 3--4 mm, claw 1--2 mm long. *Stamens* monodelphous fused adaxially. *Ovary* narrowly

oblong, 5--7 mm long, densely sericeous; style 6--7 mm long. *Fruit* velutinous, compressed, 40--50 x 5--6 mm. *Seed* red-brown to green-brown sometimes speckled, orbicular or irregular, 2--3 x 2--2.5 mm.

A. polyphyllum is very distinctive due to the upper ramification of short branches. These branches have dense foliage and bear terminal inflorescences. The small-leaved axillary branches are however absent from seedlings and coppicing specimens (*Britten 5654, Bokelmann s.n.*). In addition rejuvenated specimens bear erect inflorescences with well developed bracts while in moribund specimens inflorescences have small bracts and are often pendent and secund.

The species usually occurs on forest margins in Alexandria Forest and Highland Sourveld (Figure 64). ²⁶

- **14. *Argyrolobium crassifolium* (E. Mey.) Eckl. & Zeyh., Enum. Pl. Afr. Austr. 2: 184 (1836); Walp.: 506 (1839); Walp.: 631 (1843); Benth.: 342 (1844); Harv.: 70 (1862). Type: Uitenhage, Elandsriver Mountains, *Ecklon & Zeyher s.n.* (TCD!, neo. selected here; BM!, GRA!, PRE!, S!, SAM!, isoneo.). [Original type: eastern Cape, Zwellendam (Swellendam) below 500 ft., *Ecklon s.n.*].**

Dichilus crassifolius E. Mey.: 154 (1832). Type: as above.

Chasmone crassifolia (E. Mey.) E. Mey.: 72 (1836). Type: as above.

Chasmone goodioides Meisn.: 75 (1843) *synon. nov.* Type: Wintershoekberge, 2000 ft. Krauss 929 (G!, lecto. selected here; MO!, W!, isolecto.).

Argyrolobium goodioides (Meisn.) Walp.: 845 (1843) *synon. nov.* Type: as above.

Shrub, up to 1 m tall, erect, well branched, stems sericeous, becoming glabrous.

Leaves glabrous above, sparsely sericeous below; leaflets 6--12 x 3--8 mm, broadly obovate, apex rounded to emarginate, apiculate; petiole 3--6 (--) mm long; stipules 0.5--2 x 0.5 mm, setaceous or lanceolate. Inflorescence racemose, 1--4-flowered, terminal, becoming leaf-opposed; peduncle 7--15 (--) 20 mm long; bracts 1--2 x 0.5 mm, linear, bracteoles 0.5--1.5 x 0.25--0.5 mm. Calyx pilose, deeply bilabiate; upper lobes often united, 4--6 mm long; lower lip 6--7 mm long, lobes vestigial. Corolla yellow; standard suborbicular, 9--12 x 8--10 mm, adaxial surface sparsely sericeous, base rounded, claw 1--1.5 mm long; wings oblong to obovate, 10--11 x 4--4.5 mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw 1--2 mm long; keel cymbiform, 9--10 x 4--4.5 mm, claw 1--3 mm long. Stamens monadelphous, sheath completely fused above.

Ovary narrowly oblong, 6--8 mm long; style 3--4 mm long. Fruit sparsely sericeous, compressed, only immature fruits seen. Seed not seen.

In habit *A. crassifolium* resembles *A. parviflorum* but these species are easily separated on leaf vestiture, leaf venation and floral characters. Both species are limited to False Macchia but *A. crassifolium* occurs coastally (Figure 66).

The typification of this species is confusing. Meyer's (1832) original description was of an Ecklon specimen, presumably collect during the expedition undertaken in 1829 to Algoa Bay (Gunn & Codd 1981). The original description cites only the district Uitenhage. Meyer (1836) transferred the species to *Chasmone* and cited a more precise locality, 'Zwellendam'. Neither of these specimens were located and it is likely both were destroyed at B during World War II. Ecklon and Zeyher (1836) cite a different collection as the type and in the absence of Meyer's type material this was chosen as the neotype.

3324 (Steytlerville): Hankey, nr. Harmonie, (--DD), *Cowling* 823 (GRA). 3325 (Port Elizabeth): Elandsrivierberge, (--CA), *Ecklon & Zeyher* 1305 (BM, GRA, S, SAM); Bulkriver, (--CC), *Holland* 3857 (PRE); *Holland* 3653 (BOL); Uitenhage, (--CD), *Harvey* 931 (BM, TCD); *Krauss* 929 (G, MO); *Schlechter* 2522 (BM); *Zeyher* 2303 (G, P, PRE, S, SAM); Addo Bush, (--CD), *Story* 2760 (PRE); Backens River, (--DC), *Long* 285 (PRE); Redhouse, (--DC), *Paterson* 601 (BOL, GRA, PRE); Port Elizabeth, (--DC), *Salter s.n.* (BM). 3424 (Humansdorp): Geelhoutrivier, (--BB), *Fourcade* 2288 (BOL, PRE).

15. *Argyrolobium incanum* Eckl. & Zeyh., Enum. Pl. Afr. Austr. 2: 185 (1836); Harv.: 70 (1862). Type: eastern Cape, Bothasberg nr. Grahamstown, *Ecklon & Zeyher s.n.* (PRE!, lecto. selected here; SAM!, isolecto.).

Chasmone holosericea E. Mey. var. *incana* Meisn.: 76 (1843). Type: eastern Cape, Baviaanskloof, mountain sides, Dec. 1838, *Krauss s.n.* (B†).

Shrub, up to 2 m tall, erect, well branched, stems sericeous, becoming glabrous. Leaves sericeous; leaflets obovate to obcordate, 5–15 x 4–10 mm, apex rounded, emarginate or recurvo-mucronate; petiole 3–12 mm long; stipules setaceous to subulate, 0.5–4 x 0.2–1 mm. Inflorescence racemose to pseudo-umbellate, (1–) 3–5 (–8)-flowered, terminal, becoming leaf-opposed; peduncle sericeous; bracts subulate to lanceolate, 1–3 x 0.5–1 mm; bracteoles lanceolate, 1–3 x 0.25–1 mm. Calyx sericeous; upper lip 10–12 mm long, sinus 4–6 mm deep, lobes sometimes connate; lower lip 10–13 mm long, lobes usually connate. Corolla yellow becoming russet with age; standard orbicular, 11–15 x 10–14 mm, adaxial surface sericeous medially, base obtuse, claw 2 mm long; wings oblong to obovate, 10–14 x 4–6 (–7) mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw 2–3 mm; keel cymbiform, 9–12 x 4–5 mm, claw 2–3 mm long. Stamens monadelphous, sheath split above almost to the base. Ovary narrowly oblong, 8–10 mm long; style 3–4 mm long. Fruit sericeous, compressed, 40–60 x 4–5 mm. Seed yellow, irregular, 2–3 mm in diameter.

A. crassifolium, *A. trifoliatum* are often misidentified as *A. incanum*. The features which separate *A. crassifolium* relate to its diminutive leaves and flowers. In addition its leaflets are sparsely hairy abaxially and usually glabrous adaxially. The distinction of *A. trifoliatum* is based on the absence of trichomes on the adaxial leaflet surfaces. *A. trifoliatum* frequently produces basal coppices with long internodes and villose indumentum no similar growth has been observed in *A. incanum*.

A. parviflorum, was previously lumped with *A. incanum* however it is easily distinguished by its prominent abaxial leaf ribs and smaller flowers.

Coastal forms of *A. incanum* from Humansdorp are less than 600 mm tall and have small leaflets. Inland forms from the Baviaanskloof Mountains are taller (c. 2 m) and virgate with large leaves (Figure 64). Both forms occur in False Macchia.

16. *Argyrolobium parviflorum* T.J. Edwards in S. Afr. J. Bot. 59: 296 (1993).

Type: eastern Cape, Steytlerville, Baviaanskloof, Enkeldoorn track, Klein Rivier, *Snijman* 338 (NBG!, holo.; PRE!, iso.).

Shrub, up to 1 m tall, erect, well branched; stems velutinous, becoming glabrous. *Leaves* velutinous; leaflets, broadly obovate, 5–9 x 4–6 mm, abaxial costae prominent, reticulate, apex rounded to emarginate, apiculate; petiole 1.5–6 mm long; stipules 0.25–2 x 0.25–0.5 mm, setaceous or lanceolate, caducous. *Inflorescence* pseudo-umbellate, 1–4-flowered, terminal, becoming leaf-opposed; peduncle 4–5(–9) mm long; bracts 1–1.5 x 0.25–0.5 mm; bracteoles narrowly ovate to linear, 0.5–1 x 0.25 mm. *Calyx* velutinous, deeply bilabiate; upper lobes

Figure 63

Argyrolobium incanum. A. Calyx (bar = 2 mm); B. standard, abaxial surface (bar = 2 mm); C. wing (bar = 2 mm); D. keel (bar = 2 mm); E. flowering branch (bar = 20 mm); F. androecium (bar = 2 mm). Voucher: *Edwards & Ackermann* 478.

A

5--6 mm long, upper sinus vestigial; lower lip 7--8 mm long, lobes vestigial. *Corolla* yellow; standard suborbicular, 8--9 x 7.5--8.5 mm, adaxial surface sericeous apically, base rounded; claw 1.5--2 mm long; wings oblong to obovate, 9--9.5 x 3--3.5 mm, with lunate-lamellate sculpturing in the basal and upper central zones; claw 1--2 mm long; keel acutely cymbiform, 6.5--7 x 3 mm; claw 1--2 mm long. *Stamens* monadelphous, sheath completely fused above. *Ovary* narrowly oblong, 5--6 mm long; style 3 mm long. *Fruit* velutinous, compressed (only immature fruits seen). *Seeds* not seen.

The reticulate costae of the abaxial leaf surfaces and the small flowers make *A. parviflorum* a distinctive species. With respect to flower size it approximates *A. crassifolium* which differs in its vegetative indumentum and the absence of costae from the abaxial leaf surfaces. *A. parviflorum* is only recorded from False Macchia on the Baviaanskloof Mountains (Figure 66).

28

Sectio 5. Argyrolobium

Suffrutices, frutices et herbae infirme perennes, floribus dimorphis, foliis infirme dimorphis, foliis superis numquam filiformibus.

Type species: *A. argenteum* (Jacq.) Eckl. & Zeyh.

Herbs, suffrutices or shrubs, erect, decumbent or scandent; stems well branched, weakly perennial, sericeous to pilose, becoming glabrous; roots ligneous, perennial. *Leaves* variously sericeous to pilose; leaflets, ovate, obovate to suborbicular; apex acute to rounded, apiculate; stipules setaceous to ovate.

Inflorescence sessile or pedunculate, racemose or rarely pseudoumbellate; leaf-opposed or rarely terminal; bracts linear to ovate, bracteoles setaceous to ovate.

Flowers dimorphic. *Calyx* sericeous; deeply divided. *Corolla* bright yellow fading to russet; standard suborbicular to obovate, adaxial surface sericeous; wings obovate to oblong, glabrous or distally sericeous, often with lunate-lamellate sculpturing in the upper basal and upper central zones; keel cymbiform, glabrous or pilose along the lower margin. *Stamens* monadelphous or pseudodiadelphous, sheath fused above. *Ovary* narrowly oblong, style glabrous. *Fruit* pilose, compressed. *Seed* with asymmetric funicular tongue or symmetrical aril.

This section includes the most widespread species which embrace a wide range of forms. The production of cleistogamous flowers is limited to section

Argyrolobium. The former includes herbs with lignotubers and filiforme leaves.

We have recognised a number of very similar, sympatric species because they maintain their identity in mixed populations. This is especially true of *A. rupestre* and its allies. The section will need expansion to incorporate tropical entities.

17. *Argyrolobium tomentosum* (Andr.) Druce in Rep. Bot. Exch. Cl. Brit. Is. 1916: 605 (1917); Burtt Davy: 394 (1926); Wilczek: 277 (1953); Polhill: 162 (1968); Ross: t. 1602 (1970). Type: t. 237 in Andrew's Botanical Repository 4 (1802), from cultivated plants at Hammersmith Nursery, London, seed from Cape Province.

Cytisus tomentosus Andr.: t. 237 (1802). Type: as above.

Tephrothamnus tomentosus (Andr.) Sweet: 126 (1830). Type: as above.

Chasmone andrewsiana E. Mey.: 74 (1836), *nom. illegit.* Type: Natal, between Omcomas and Port Natal, *Drège s.n.* (K!, syn.); near Enon, *Drège s.n.* (syn.).

Chasmone andrewsiana E. Mey. var. *umbellata* E. Mey.: 74 (1836), *nom. illegit.* Type: Port Natal, near the Bay, *Drège s.n.* (not traced).

Argyrolobium andrewsianum (E. Mey.) Steud.: 129 (1840); Benth.: 348 (1844); Harv.: 75 (1862); Harms: 178 (1917); Bak.f.: 64 (1926).

Argyrolobium andrewsianum var. *racemosum* Harv.: 75 (1862), *nom. nud.*

Argyrolobium tomentosum var. *racemosum* (Harv.) Burtt Davy: 394 (1926)

nom. nud.

Argyrolobium andrewsianum var. *pauciflorum* Harv.: 75 (1862), *nom. nud.*

Argyrolobium andrewsianum var. *helvolum* Harv.: 75 (1862). Type: Natal,

Gueinzius s.n. (G!, lecto. selected here).

Dichilus ciliatum Spreng.f.: 20 (1828). Type: Without precise locality, Zeyher 273 (*not traced*).

Trichasma ciliatum Walp.: 510 (1839); Walp.: 630 (1843). Type: as above.

Argyrolobium shireense Taub.: 207 (1895); Bak.f.: 68 (1926); Wilczek: 279 (1953). Type: Malawi, Shire Highlands, Buchanan 466, 481 & Last s.n. (K!, isosyn.).

Argyrolobium stuhlmannii Taub.: 207 (1895); Bak.f.: 65 (1926); Wilczek: 278 (1953). Type: Rwanda/Uganda border, W. Mpororo, Stuhlmann 3108 (B†).

Argyrolobium angustistipulatum De Wild.: 518 (1924); Bak.f.: 67 (1926). Type: Congo Republic, Kivu Province, Boswenda, Bequaert 6088 (BR!, holo.).

Suffrutex, 0.1--1 m tall, prominently branched, stems perennial, sparsely sericeous. *Leaves* monomorphic; leaflets ovate, elliptic or obovate, 10--50 x 7--30 mm, glabrescent to sparsely sericeous, apex rounded, apiculate, petiole 5--38 mm long; stipules subulate to lanceolate, 1--9 x 0.25--2 (--3) mm. *Inflorescence* 1--25 (--30)-flowered, racemose to pseudoumbellate, leaf-opposed; bracts linear-lanceolate to lanceolate, 1--6 x 0.25--1 mm; bracteoles minute 1--3 x 0.25 mm.

Flowers dimorphic. *Calyx* sericeous, upper lip 5–10 mm long, sinus 3–7 mm deep; lower lip 6–10 mm long, lobes 1–2 mm long, medial lobe linear. *Corolla* yellow, becoming russet; standard suborbicular, 8–15 x 11–15 mm, adaxial surface sparsely sericeous, base cordate, claw 1–1.5 mm long; wings obovate, 8–12 x 5–7 mm, lacking sculpturing, often sericeous distally, claw 0.75–1.5 mm long; keel cymbiform, 5–8 x 3–4 mm, claw 1–2.5 mm long. *Stamens* monodelphous split adaxially. *Ovary* narrowly oblong, 4–6 mm long, densely sericeous; style 3–5 mm long. *Fruit* sericeous, compressed, linear, 30–50 x 4–5 mm. *Seed* red-brown to black, orbicular or irregular, 2 x 2.5 mm.

A. tomentosum is widespread in temperate woodlands, its disjunct afromontane distribution suggests antiquity (Figure 67). Considerable variability in plant size and indumentum has resulted in the complex synonymy which was rationalised by Polhill (1968). In southern Africa this species could be confused with *A. frutescens* which however, lacks cleistogamous flowers, has obovate standard petals and shortly petiolate leaves.

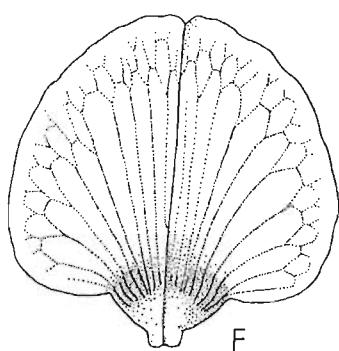

Without precise locality: *Cooper* 1178 (E); *Junod* 1721 (G); *Gueinzius* 315 (G); *Burchell* 5217 (E, G); *Drège* s.n. (G); *Zeyher* 456 (G); *Drège* s.n. (O); *Ecklon & Zeyher* s.n. 18. *Argyrolobium humile* Phillips in Ann. S. Afr. Mus. 9: 120 (1913). Type:
Griqualand East, Mt. Malowe, *Tyson* 1259 (BM!, lecto. selected here; BOL!, G!, UPS!, isolecto.).

Herb, up to 0.25 m tall, erect to decumbent; stems sparingly branched, glabrescent to pilose, becoming glabrous; roots ligneous, perennial. Leaves pilose to sericeous on both surfaces; leaflets, broadly obovate to broadly elliptic, 15--28 x 8--16 mm; petiole sericeous to pilose, 1--2 (--4) mm long; apex rounded,

Figure 67

Argyrolobium tomentosum. A. Flowering branch (bar = 20 mm); B. calyx (bar = 2 mm); C. fruits (bar = 4 mm); D. keel (bar = 2 mm); E. wing (bar = 2 mm); F. standard, abaxial surface (bar = 2 mm). Voucher: *Edwards* 443.

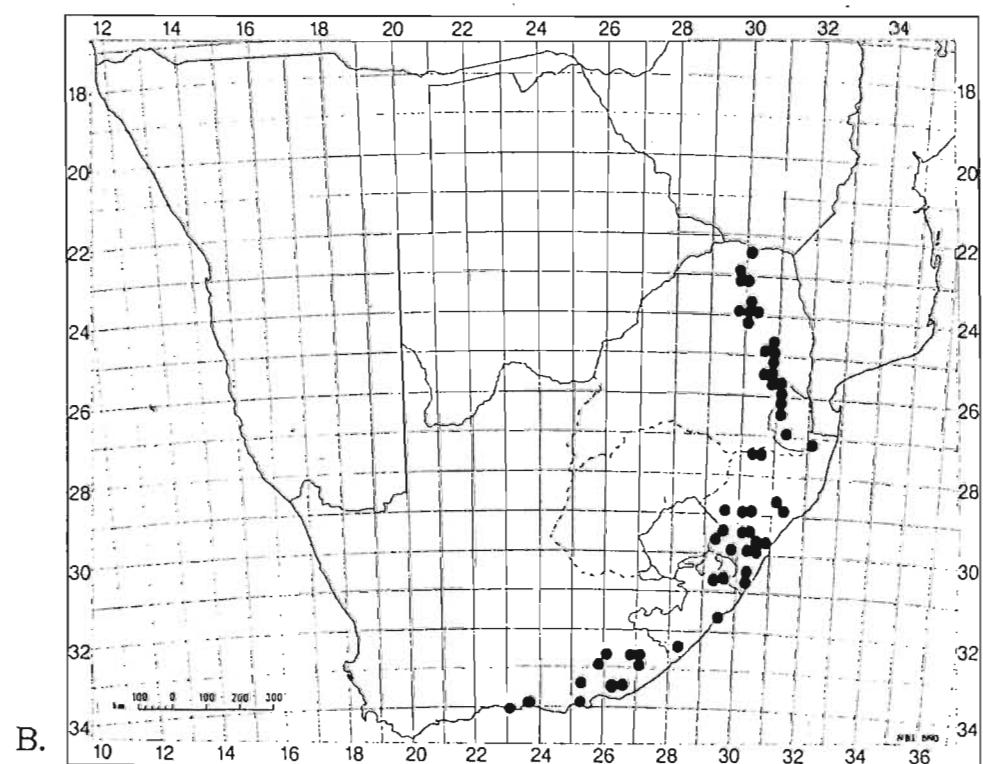

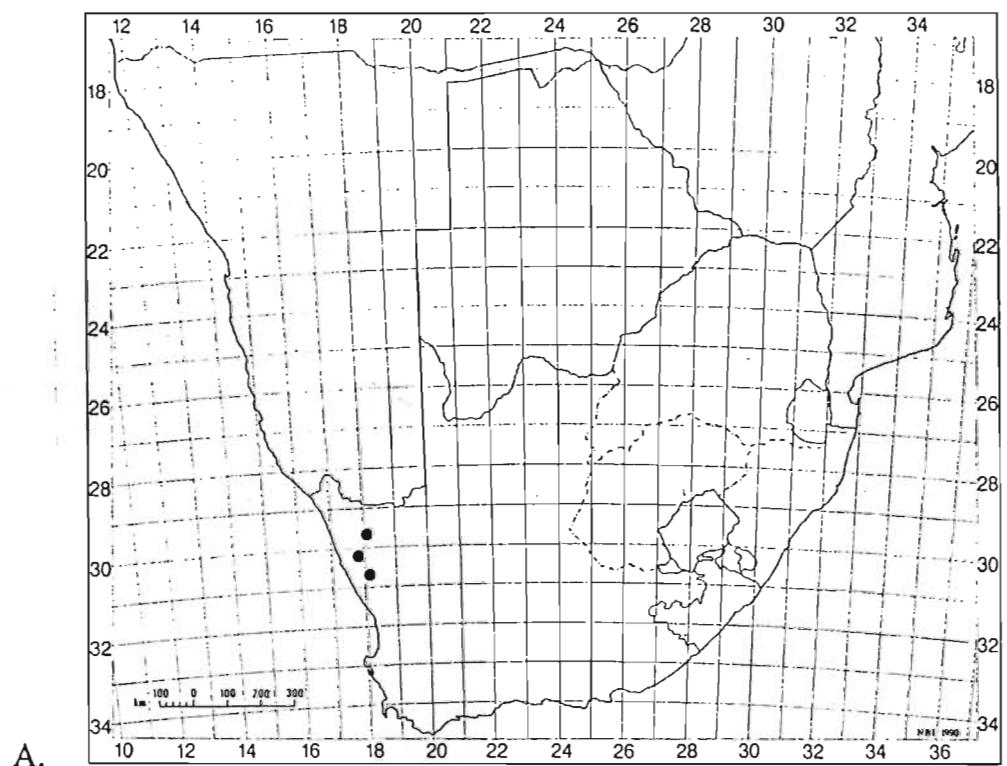

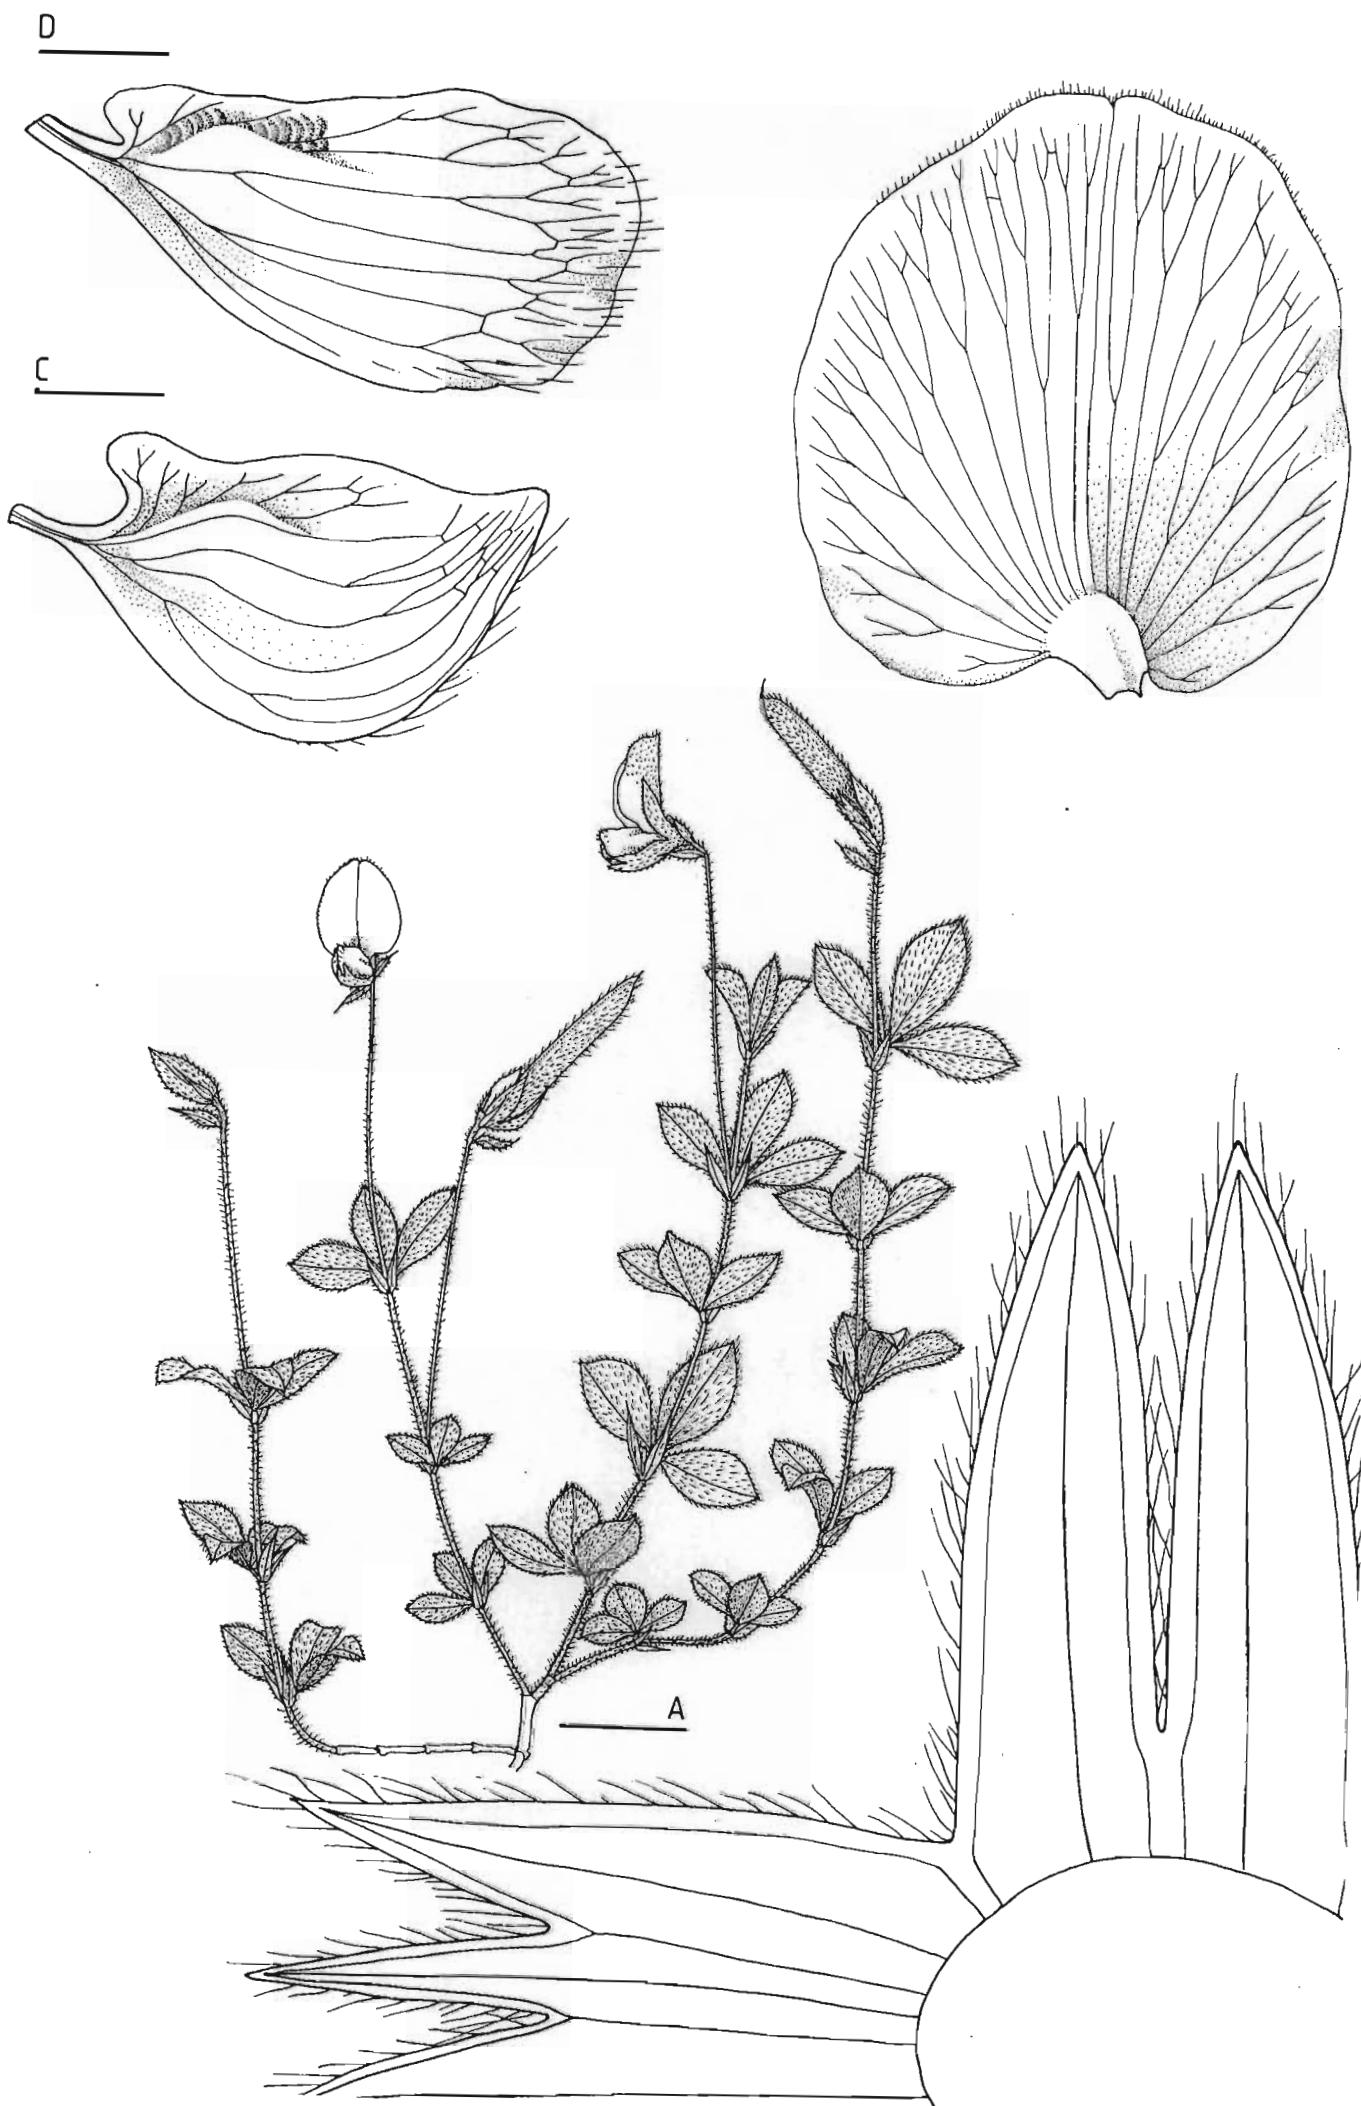

Figure 68. Recorded distribution of A. *A. petiolare* & B. *A. tomentosum*.

apiculate; stipules lanceolate to narrowly ovate, (2--) 4--8 x 1--3 mm. *Inflorescence* 1--2 (--4)-flowered, initially terminal but becoming leaf-opposed; peduncle (20--) 30--45 mm long; bracts ovate, 2.5--5 x 0.75--1 mm, bracteoles, linear, 1.5--3 x 0.25--0.5 mm. *Flowers* dimorphic. *Calyx* pilose or rarely sericeous, deeply bilabiate; upper lobes 9--12 mm long, upper sinus 7--10 mm, lower lip 9--12 mm long, lobes 4--6 mm long. *Corolla* bright yellow fading to russet; standard suborbicular, 13--16 x 13--18 mm, adaxial surface sparingly sericeous, base cordate, claw 1--2 mm long; wings oblong to obovate, 10--13 x 4--5 mm, sparingly sericeous, claw 1--2 mm long, with 3--4 rows of lunate-lamellate sculpturing in the upper basal zone; keel cymbiform, 8--11 x 5--6 mm, glabrous or sparsely sericeous along the suture, claw 1--2 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 5--7 mm long; style 4--5 mm long. *Fruit* sparsely pilose, up to 45 x 5 mm. *Seed* suborbicular, laterally compressed, 1.75--2 x 2 mm, light to dark brown, hilar rim raised, hilar tongue white, asymmetrical.

A. humile is sometimes difficult to distinguish from *A. rupestre* and *A. ascendens*, diagnostic differences are discussed under the latter. The three are sympatric in parts of Natal and the Transkei but no evidence of hybridisation has been found. Near Pietermaritzburg populations of almost exclusively cleistogamous *A. humile* occur (*Edwards* 696 & 829). The minimal reduction of cleistogamous inflorescences in *A. humile* is cogent with species status. Cleistogamous flowers

of *A. rupestre*, *A. ascendens* and *A. rotundifolium* always have diminutive calyces.

This species is common in moist grassland of the eastern Cape and Natal occurring mainly in Highland and Dohne Sourveld (Figure 74).³⁰

19. *Argyrolobium ascendens* (E. Mey.) Walp. in Linnaea 13: 507 (1839); Walp.: 631 (1843); Harv.: 75 (1862). Type: Natal, in grassland, between Omcomas (Nkomani River) and Omblas, below 500', *Drège* (Vc, 24) (K!, lecto. selected here; G!, MO!, P!, TCD!, S!, isolecto.).

Chasmone ascendens E. Mey.: 73 (1836). Type: as above.

Argyrolobium longipes N.E. Br.: 254 (1897), *synon. nov.* Type: Transvaal, Berea Ridge, Barberton, *Galpin* 1305 (BOL!, K!, PRE!, isosyn.); Natal, Tugela, *Gerrard & McKen* 1764, 1765 (K!, lecto. selected here; BM!, K!, TCD!, W!,

isolecto.).

Herb, up to 0.4 m tall, decumbent or scandent; stems weakly perennial, well branched, sericeous, becoming glabrous; roots ligneous, perennial. *Leaves* sericeous on both surfaces; leaflets, narrowly obovate to elliptic, 8--27 x 2--11 mm; petiole sericeous, (1--) 3--5 (–7) mm long; apex acute, apiculate; stipules lanceolate to ovate, (2--) 3--5 (–10) x (0.5--) 1--3 (–4) mm, apex attenuate. *Inflorescence* pseudo-umbellate, 2--6-flowered, terminal but becoming leaf-opposed; peduncle 60--150 mm long; bracts ovate, 3--7 x 1--3 mm, bracteoles, linear, 1--5 x 0.5--1 mm. *Flowers* dimorphic. *Calyx* sericeous, deeply bilabiate; upper lobes 5--7 mm long, upper sinus 5 mm, lower lip 5--7.5 mm long, lobes 2.5--3 mm long. *Corolla* bright yellow fading to russet; standard broadly obovate, 11--14 x 9--10 mm, adaxial surface sparingly sericeous, base cuneate, claw 1--2 mm long; wings oblong to obovate, 9--11 x 3--4 mm, sparingly sericeous, sculpturing vestigial, claw 1--2 mm long; keel cymbiform, 9--11 x 4--5 mm, glabrous to sparsely sericeous along the suture, claw 1--2 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 5--7 mm long; style 4--5 mm long. *Fruit* sparsely sericeous, up to 45 x 4--5 mm. *Seed* suborbicular, laterally compressed, 1.75--2 x 3 mm, light to dark brown, often speckled, aril white.

A. ascendens is distributed from southern Natal into the eastern Transvaal. Plants are slightly variable in leaf size but these differences manifest themselves within single populations. The prominent, symmetrical aril is diagnostic for this species (Figure 71).

A. ascendens is closely related to *A. rupestris* and material lacking seed is sometimes difficult to place. The flowers of *A. ascendens* are smaller and are borne atop longer peduncles, its petioles are shorter and its stipules are larger. The leaflets of this species are usually elliptic with acute apices while those of *A. rupestris* are usually obovate with rounded apices. *A. humile* is also commonly confused with *A. ascendens*. It can be distinguished by its fewer, larger flowers, pilose indumentum and larger rounded leaflets.

This species occurs commonly in Ngongoni Veld but extends into a variety of grassland types (Figure 74).

Without precise locality: Tugela, *Gerrard & McKen 1765 & 1764* (BM, TCD).
 2529 (Witbank): Middelburg, (--CD), *Kassner 101* (BR). 2530 (Lydenburg): Elandspruitbergen, (--AA), *Schlechter 3839* (B, BOL, BR, C, E, G, PRE);

20. *Argyrolobium rotundifolium* T. J. Edwards in Bothalia 23: 77 (1993a).

Type: Pietermaritzburg, between Peacevale & Drummond, *Edwards & Ackermann* 329 (NU!, holo.; K!, E!, PRE!, iso.).

Herb, up to 0.15 m tall, but usually prostrate; stems well branched, weakly perennial, shortly rufous-tomentose, becoming glabrous; roots ligneous. *Leaves* moderately tomentose adaxially, densely tomentose abaxially; leaflets broadly obtuse to rounded, 14--32 x 10--25 mm, apiculate; margins densely rufous-tomentose; stipules free, setaceous to lanceolate, 3--10 x 1.5 mm. *Inflorescence* pseudo-umbellate, 1--4 (--6)-flowered, initially terminal but becoming leaf-opposed; peduncle (30--) 40--150 mm long; bracts linear or narrowly elliptic, up to 6 x 1 mm, bracteoles linear, up to 3 mm long. *Flowers* dimorphic. *Calyx* sparsely to densely pilose; upper lobes 8--10 mm long, lower lip 8--11 mm long, lobes 3--4 mm long. *Corolla* bright yellow becoming russet; standard suborbicular, 11--14 x 12--14 mm, adaxial surface sericeous, base cordate, claw 1--1.5 mm long; wings obovate, 9--12 x 4.5--6 mm, without sculpturing, distally pilose, claw 1.5--2 mm long; keel cymbiform, 8--10 x 4.5--5.5 mm, pilose on the lower margin, claw 1.5--2.5 mm. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 6--8 x 1--2 mm; style 3--4 mm long. *Fruit* rufous-pilose, compressed, 30--45 x 5 mm. *Seed* suborbicular, slightly compressed, 2--3 mm in diameter, yellow to light brown, hilar rim raised, hilar tongue white,

asymmetrical.³²

A. rotundifolium is allied to *A. rupestris* but is distinguished by its consistently prostrate habit (*A. rupestris* is better described as ascending or decumbent), broadly elliptical to orbicular leaflets, shortly rufous-tomentose indumentum and the lack of sculpturing on its wing petals. This species is predominantly coastal in distribution while *A. rupestris* is limited to inland areas (Figure 74). In southern Natal *A. rupestris* approaches the coast on the high lying areas around Kokstad and Harding however no contact zones with *A. rotundifolium* have been recorded.

Without precise locality: *Flanagan* 3675 (PRE); *Gerrard* 178 (BM); *Wood* 11411 (NH). 2632 (Bela Vista): between Ingwavuma and Manyansenii, (--CC), *Moll* 4561 (PRE). 2732 (Ubombo): northern arm of Lake Sibaya, (--BC), *Ward* 546 (NH). 2831 (Nkandla): Itala Nature Reserve, (--CA), *Schrile* 1180 (NH); *Germishuizen* 2232 (PRE); Eshowe, (--CD), *Grobbelaar* 2328 (PRE); Ngoye, (--DC), *Huntley* 852 (NU); *Stirton* 454 (PRE). 2832 (Mtubatuba): Hluhluwe Game Reserve, Mbhombe, (--AA), *Hitchins* 598 (PRE); Mngqabatheki, (--AB), *Scott-Smith* 41 (NH, NU). 2930 (Pietermaritzburg): Phoenix, (--CA), *Schlechter* 3128 (B, BR, GRA); Town Hill, (--CB), *Fisher* 335 (NU); *Hilliard* 8209 (E, NU); *Huntley* 87 (E, NU); Lagerfarm, KwaSangwane Hill, (--DA), *Balkwill* 4613

21. *Argyrolobium rupestre* (E. Mey.) Walp. ssp. *rupestre* in Linnaea 13: 508 (1839); Benth.: 345 (1844); Harv.: 73 (1862); Bak. f.: 63 (1926); Polhill: 157 (1968). Type: Cape Province, Stormberg, 5000-6000', *Drège* s.n. (K!, lecto.; BM!, K!, isolecto.).

Chasmone rupestris E. Mey.: 74 (1836). Type: as above.

Argyrolobium rhodesicum Bak. f.: 64 (1926). Type: Zimbabwe, Umtali, *Rogers* 4029 (K!, holo.; BM!, iso.).

Argyrolobium tysonii Harms: 181 (1917), *synon. nov.* Type: Natal,

Kokstad, Tyson 455 (BOL!, holo.; G!, K!, SAM!, UPS!, W!, iso.).

Argyrolobium rogersii N.E. Br. in Burtt Davy: 394 (1926), *synon. nov.*

Type: Transvaal, Pietersburg, the Downs, *Rogers 22061* (K!, lecto. selected here; PRE!, isolecto.).

Herb or suffrutex up to 0.3 m tall, decumbent or scandent; stems well branched, weakly perennial, sericeous to pilose, becoming glabrous. *Leaves* sparsely to densely sericeous on both surfaces; leaflets 10--30 x 3--17 mm, narrowly or broadly ovate to obovate; petiole sericeous to pilose, 5--16 mm long; apex acute to rounded, mucronate; stipules 2--5 x 0.5--2 mm, setaceous to lanceolate.

Inflorescence pseudo-umbellate, 1--5-flowered, initially terminal but becoming leaf-opposed; peduncle 5--12 mm long; bracts linear, 2--3.5 x 0.5 mm, bracteoles 1--2 x 0.5 mm. *Flowers* dimorphic. *Calyx* sparsely to densely sericeous; upper lobes 5--9 mm long; lower lip 5--10 mm long, lobes 2.5--4 mm. *Corolla* bright yellow fading to russet; standard suborbicular, 10--14 x 8--12 (--15) mm, adaxial surface sericeous, base cordate, claw 1 mm long; wings obovate, 8--11 x 3--5 mm, glabrous, with lunate sculpturing in the upper basal and upper central zones, claw 1--2.5 mm long; keel cymbiform, 7--9 x 4--5 mm, glabrous, claw 1--2 mm long. *Stamens* monadelphous, sheath fused above. *Ovary* narrowly oblong, 5--6 mm long; style 2.5--3 mm long. *Fruit* sparsely pilose, compressed, up to 20 x 5 mm. *Seed* suborbicular, slightly compressed, 2--3 mm in diameter, speckled dark brown, hilar rim raised, hilar tongue asymmetrical.

A. rupestre is widespread and perhaps best treated as a species complex. Polhill (1968) in his revision of *Argyrolobium* for Tropical Africa recognised four subspecies. He included all the southern African material within the type subspecies. *A. rupestre* is usually associated with afromontane vegetation. *A. tysonii* is indistinguishable and is reduced to synonymy.

A. rupestre is frequently misidentified as *A. ascendens* which differs in its upright habit and very short petioles, the stipules are also usually broader than those of *A. rupestre*. In *A. ascendens* the funicle develops into a prominent symmetrical aril while in *A. rupestre* only an asymmetrical tongue of funicular tissue remains attached to the seed.

22. *Argyrolobium campicola* Harms in Ber. Deutsch. Bot. Ges. 35: 182 (1917); Edwards: 296 (1993). Type: Transvaal, highveld between the Drakensberg and Pretoria, *Wilms* 271 (B†, holo.; BM!, icono.).

Herb 0.1–0.3 m tall, erect or decumbent; stems, weakly perennial, pilose; roots

ligneous, perennial. *Leaves* pilose on both surfaces; leaflets 8--24 x 3.5--9 mm, obovate to elliptic; apex acute to rounded, mucronate; petiole pilose, 2--5 mm long; stipules foliaceous, connate in the lower half, 6--20 x 2--8 mm. *Inflorescence* 1-flowered, initially terminal but becoming leaf-opposed; peduncle 30--65 mm long; bracts linear or setaceous 3--9 x 0.25--2 mm; bracteoles linear or setaceous 1--5 x 0.25--1 mm. *Flowers* dimorphic. *Calyx* pilose, deeply bilabiate; upper lobes 8.5--11 mm long, upper sinus 6--9 mm; lower lip 9--11 mm long, lobes 3--4 mm long. *Corolla* bright yellow fading to russet; standard suborbicular, 11--16 x 8.5--14 mm, adaxial surface sparingly sericeous, base cordate; claw 1--2 mm long; wings oblong to obovate, 8--11 x 3.5--4 mm, sparingly sericeous; claw 1--2 mm long, with vestigial sculpturing; keel cymbiform, 8--10 x 4--5 mm, sometimes sparingly sericeous along the lower suture; claw 1--2 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 4--5 mm long; style 3--4 mm long. *Fruit* sparsely pilose, 30--55 x 3.5--4 mm. *Seeds* suborbicular, laterally compressed, 1.75--2.5 mm, light to dark brown. ³³

A. campicola was described in 1917 but the name has not received widespread recognition. The destruction of the type material in Berlin and the relative paucity of collections have probably contributed to this. Collections of *A. campicola* have

Figure 73

Argyrolobium campicola. A. Habit (bar = 10 mm); B. leaf and connate stipules, adaxial surface (bar = 3 mm); C. standard, abaxial surface (bar = 2 mm); D. keel (bar = 2 mm); E. wing (bar = 2 mm); F. calyx (bar = 2 mm). Voucher: Shirley s.n.

been confused with *A. pauciflorum* Eckl. & Zeyh. The former is easily distinguished by its large basally connate stipules and short petioles.

The species occurs in Highland and Dohne Sourveld (Figure 74).

Without precise locality: Transvaal highveld between the Drakensberg and Pretoria, Wilms 271 (BM [drawing of the type]). 2528 (Pretoria): Bronkhorstspruit, Pienaarsriver, (--CA), De Winter 5978 (PRE); Onderstepoort, (--CA), Dr. Theiler's Lab. 14819 (PRE); Pretoria University, (--CA), Kies 344 (BOL, PRE); Queenswood, (--CB), Ried 1175 (PRE); Pienaar's River, Silverton, (--CB), Merxmuller 177 (BR). 2628 (Johannesburg): Germiston, Roodekop Station, (--AA), Codd 3630 (PRE); Geduld, Witwatersrand, (--AB), Moss 16025 (BM). 2727 (Kroonstad): Leeuspruit & Vredefort, (--AB), Bartlett-Hamilton s.n. 23. *Argyrolobium sericoseminum* Harms in Ber. Deutsch. Bot. Ges. 35: 181 (1917). Types: Natal, Weenen, 1300-1700 m, Wood 5453 (B†; BM!, BOL!, E!, PRE!, isosyn.); Wood 7194 (B†; BM!, lecto. selected here; E!, NBG!, PRE!, isolecto.).

Herb up to 0.4 m tall, decumbent or scandent; stems well branched, weakly perennial, sericeous to pilose, becoming glabrous; roots ligneous, perennial. *Leaves* sericeous to pilose on both surfaces; leaflets, narrowly obovate to elliptical, 10–36 x 4–12 mm, strongly conduplicate, reflexed; apex acute to rounded, apiculate; petiole sericeous to pilose, 4–12 (–18) mm long; stipules glabrous above, ovate to lanceolate, 4–12 x 1.5–5 (–8) mm, apex attenuate. *Inflorescence* pseudo-umbellate, 1–6-flowered, initially terminal but becoming leaf-opposed; peduncle 10–45 mm long; bracts narrowly ovate to setaceous, 2.5–7 x 0.5–1.5 mm, bracteoles linear to setaceous, 1–5 x 0.5–1 mm. *Flowers* dimorphic. *Calyx* sericeous to pilose, deeply bilabiate; upper lobes 9–10 mm long, upper sinus 5.5–8 mm, lower lip 10–12 mm long, lobes 3–5.5 mm long. *Corolla* bright yellow fading to russet; standard broadly obovate, 11–13 x 9–12 mm, adaxial surface densely sericeous, base rounded, claw 1–1.5 mm long; wings oblong to obovate, 8–10 x 3.75–5 mm, sparingly sericeous, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw 1–2 mm long; keel cymbiform, 8–9 x 4.5–5 mm, sericeous along the lower suture, claw 1–2 mm long. *Stamens* pseudodiadelphous, vexillary filament fused basally for 1–2 mm. *Ovary* narrowly oblong, 6–8 mm long; style 4–5.5 mm long. *Fruit* pilose, compressed, 18–35 x 5–6 mm. *Seed* suborbicular, laterally compressed, 1.75–2 x 2–3 mm, light to dark brown.

A. sericosemium is closely allied to *A. marginatum* but the leaflets are

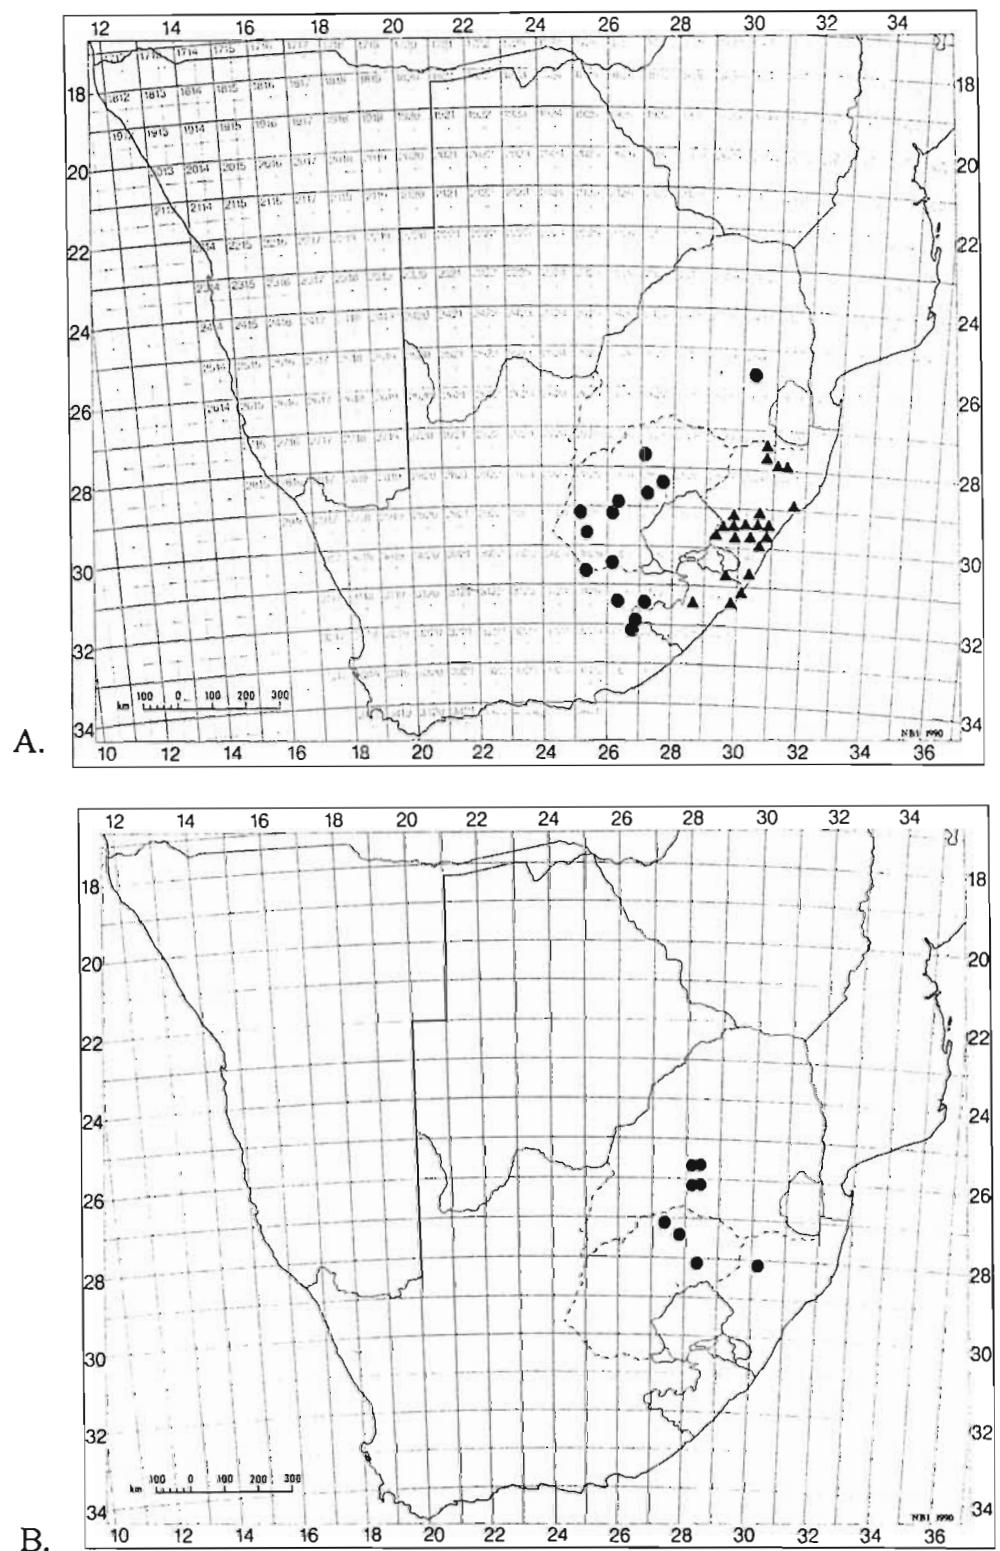

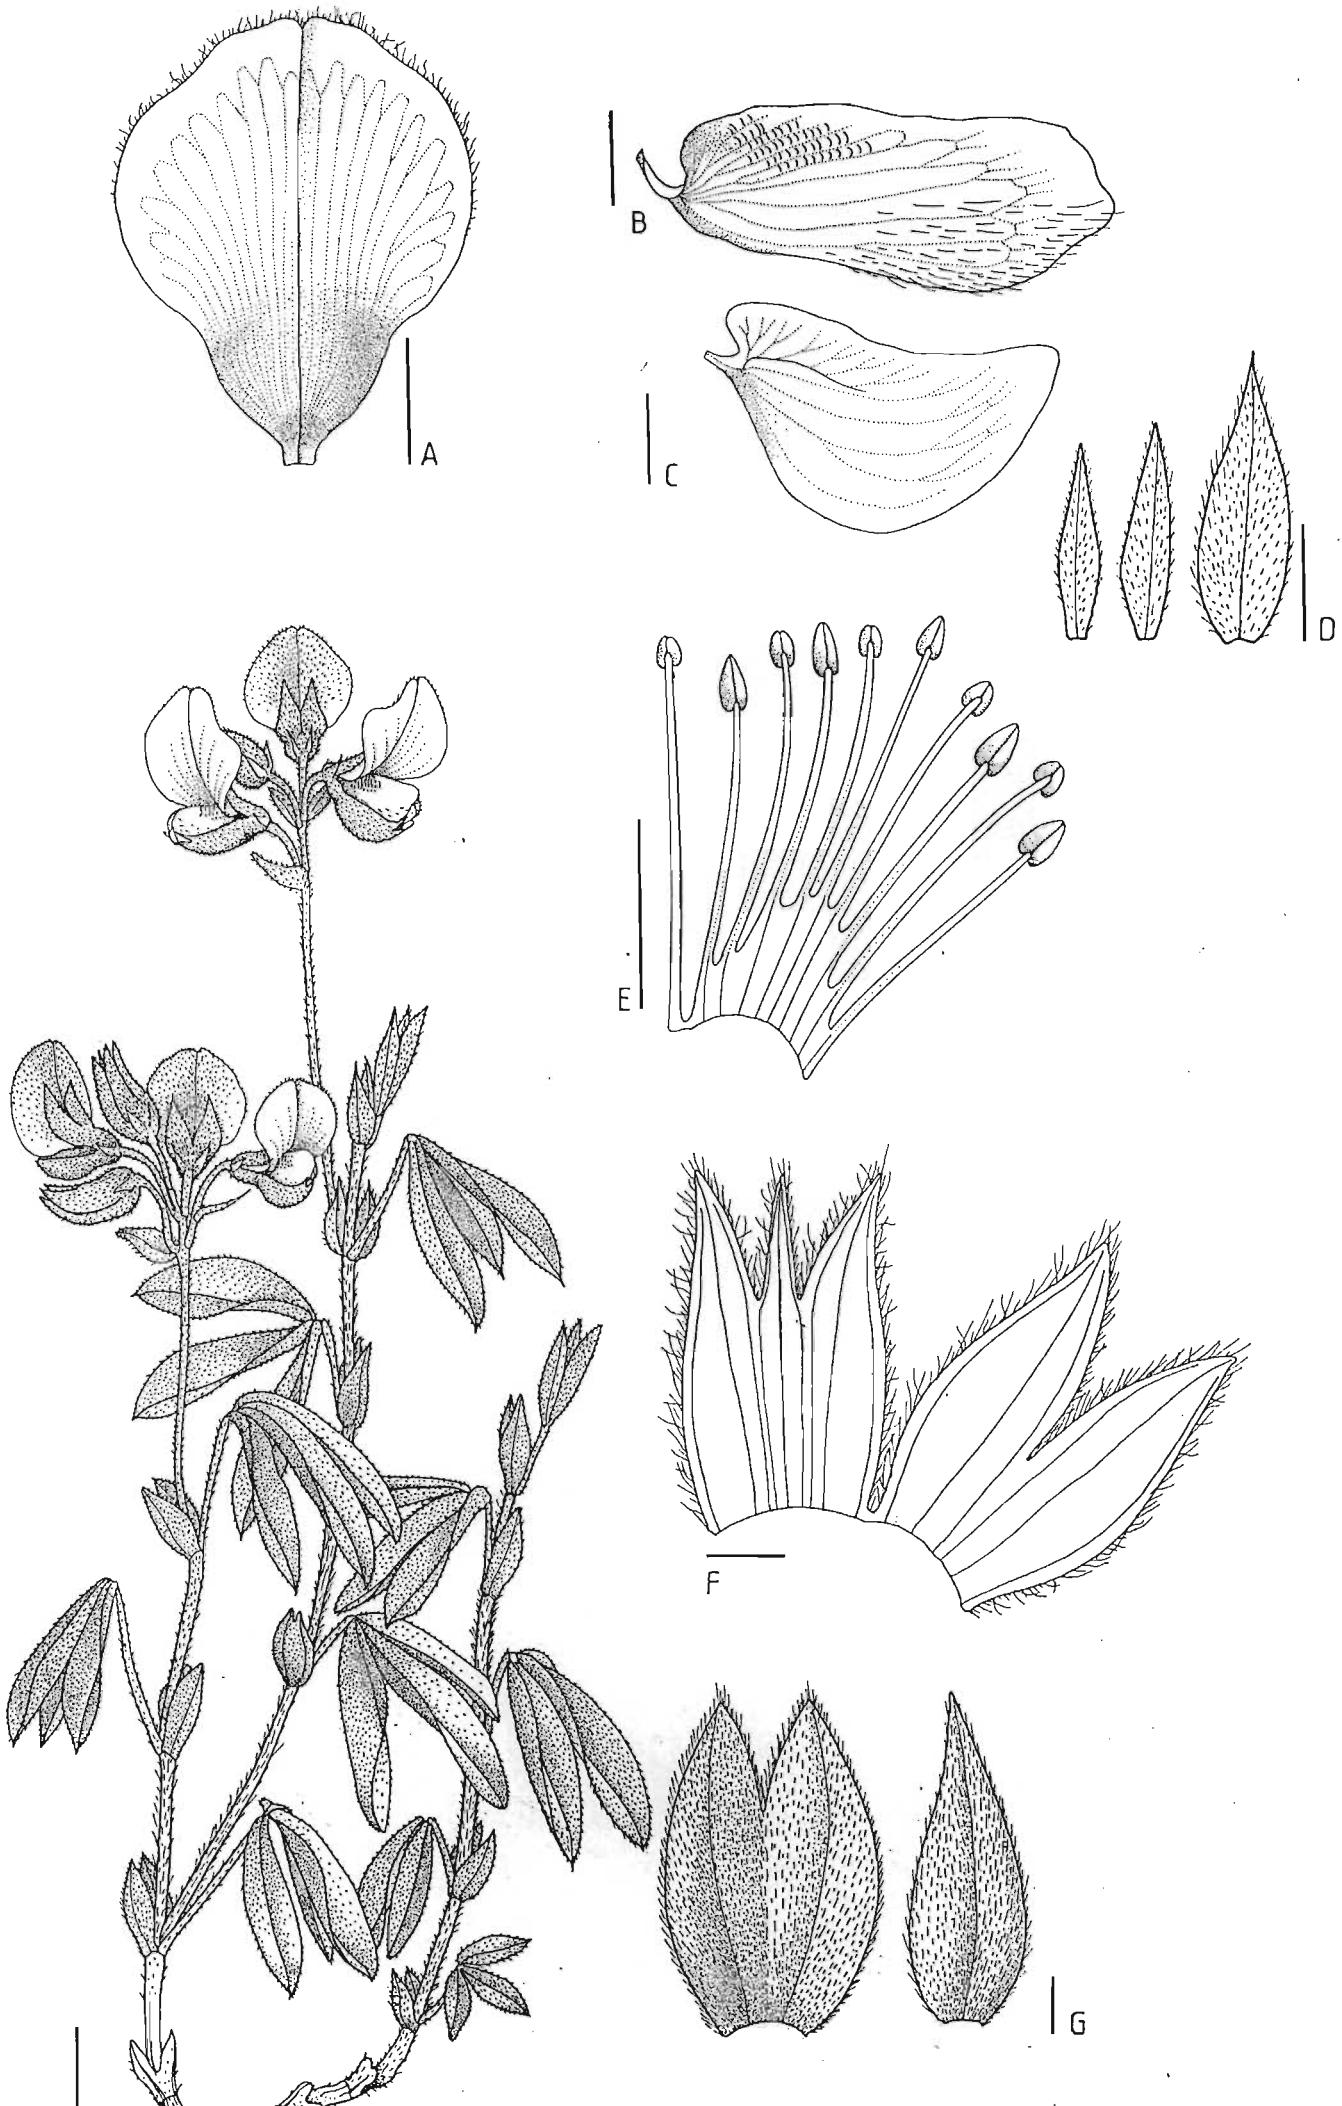

Figure 74. Recorded distribution of A. *A. humile* ▲ and *A. pauciflorum* ● & B. *A. campicola*.

conduplicate and pendant and the inflorescences are few-flowered. Populations on Bulwer Mountain display individuals of this facies mixed with individuals of *A. marginatum* and further field studies may necessitate the sinking of these taxa. Staminal fusion of *A. sericosemium* is highly unstable but tends towards diadelphy although the vexillary filament is fused basally.

The species is restricted to the Natal Drakensberg in Highland and Dohne Sourveld (Figure 76).

24. *Argyrolobium marginatum* H. Bol. in J. Linn. Soc. (Bot.) XXV: 161 (1889). Type: East Griqualand, Mt. Malowe near Clydesdale, *Tyson* 2054 (K!, lecto., selected here; BOL!, PRE!, SAM!, isolecto.); Natal, Illovo, *Wood* 1852 (NH!, PRE!, isosyn.); Orange Free State, Nelson's Kop, *Cooper* 872 (BOL!, syn.).

Argyrolobium sankeyi Dümmer: 273 (1912), *synon. nov.* Type: Orange Free State, Harrismith, *Sankey* 43 (K!, holo.).

Herb up to 0.5 m tall, decumbent or scandent sometimes erect; stems well branched, weakly perennial, sericeous to densely villous, becoming glabrous;

Figure 75

Argyrolobium sericosemium. A. Habit (bar = 20 mm); B. wing (bar = 2 mm); C. keel (bar = 2 mm); D. bract and bracteoles (bar = 2 mm); E. androecium (bar = 2 mm); F. calyx, inner surface (bar = 2 mm); G. fused and free stipules (bar = 2 mm). Voucher: *Edwards* 337.

roots ligneous, perennial. *Leaves* pilose adaxially, densely pilose to tomentose abaxially and along the margin; leaflets, narrowly obovate to elliptical, 15–35 x 8–17 (–24) mm, apex acute to rounded, apiculate; petiole pilose to densely tomentose, 3–13 mm long; stipules glabrous above, ovate to lanceolate, usually partially fused basally, 6–12 x 1.5–3 mm, apex attenuate. *Inflorescence* pseudo-umbellate, 6–10 (–16)-flowered, terminal but sometimes becoming leaf-opposed; peduncle 4–50 mm long; bracts narrowly ovate to ovate, 5.5–10 x 1.5–3 mm, bracteoles narrowly ovate to linear, 4–7 x 0.75–1.75 mm. *Flowers* dimorphic. *Calyx* pilose, deeply bilabiate; upper lobes (7–) 8–12 (–15) mm long, upper sinus 5–10 mm, lower lip (10–) 12–18 mm long, lobes 5–10 mm long. *Corolla* bright yellow fading to russet; standard suborbicular, 10–15 x 10–16 mm, adaxial surface densely sericeous, base rounded, claw 1.5–2 mm long; wings oblong to obovate, 9–13 x 4–5.5 mm, sparingly sericeous, with lunate-lamellate sculpturing in the upper basal and upper central zones, claw 1–2 mm long; keel cymbiform, 8–11 x 4–5.5 mm, sericeous along the lower suture, claw 1–2 mm long. *Stamens* monadelphous. *Ovary* narrowly oblong, 6–7.5 mm long; style 5–6.5 mm long. *Fruit* pilose, 13–26 x 4–5 mm. *Seed* suborbicular, laterally compressed, 1.5–2 mm in diameter, light to dark brown sometimes speckled, hilar rim asymmetrical.

A. marginatum is the most robust member of the *A. rupestre* alliance and produces well developed, congested racemes. Partial fusion of the foliaceous stipules is

distinctive but is absent in northern specimens. Here the species approaches *A. rupestre* in form but the stipules are broadly lanceolate and the plants have larger leaves. The type collection of *A. sankeyi* is from these northern limits and this may explain Dümmer's recognition of a new species. A broad species concept is taken in this revision due to the continuity of the variation in *A. marginatum*. It is most closely allied to *A. sericosemium* and diagnostic characters are discussed under that species.

The species occurs across a range of altitude and vegetation types but is restricted to sourveld (Figure 76).

Without precise locality: Port Natal, *Gerrard & McKen* 1762 & 2125 (TCD).

Herbaceous perennial, up to 0.25 m tall, erect or decumbent, sparingly to moderately branched, stems sericeo-pilose, weakly perennial. Roots ligneous, perennial. Leaves often slightly dimorphic, sericeous, weakly or markedly conduplicate, adaxial surface sparingly sericeous to glabrous; leaflets, linear to obovate, 7–40 x 2–10 mm, with prominent venation; petiole sericeous, prominent below, reduced above, 1–8 mm long; apex acute to rounded, apiculate; stipules linear-lanceolate, 4–10 x 0.5–1 mm, apex attenuate. Inflorescence fascicled, 1–2(–3)-flowered, terminal but becoming leaf-opposed; peduncle 20–40 mm long; bracts linear, 2.5–5 x 0.5 mm, bracteoles, setaceous or absent. Flowers dimorphic. Calyx sericeous, deeply bilabiate; upper lobes 5–7 mm long, upper sinus 3.5–5 mm, lower lip 6.5–8 mm long, lobes 2–3.5 mm long. Corolla bright

yellow fading to russet; standard broadly obovate to suborbicular, 9–12 x 10–12 mm, adaxial surface sericeous, base cuneate, claw 0.5–1 mm long; wings oblong to obovate, 7–10 x 3–3.5 mm, sparingly sericeous, with ill defined sculpturing in the upper basal and upper central zones, claw 0.5–1.5 mm long; keel cymbiform 7–9 x 3.5–4 mm, glabrous, claw 0.5–1.5 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 4–6 mm long; style 3–4 mm long. *Fruit* sparsely sericeous, 25–45 x 3–4.5 mm. *Seed* suborbicular, laterally compressed, 2.5 x 2–3 mm, red-brown to dark brown.

The concept of *A. molle* has been broadened to include a wide variety of forms. Plant stature is influenced by environmental conditions and large differences were not apparent in cultivated plants from a wide geographic range. Herbarium specimens vary in leaflet shape, size and vestiture but this also occurs within populations and therefore is not indicative of different species. No differences were observed in cultivated plants from the eastern Cape and Natal.

A. patens is reduced to synonymy because its identity is based on its diminutive leaflets and decumbent habit. Moribund specimens of *A. molle* are decumbent with small internodes and leaflets. Precocial, cleistogamous flowering and phenotypic plasticity may explain the wide distribution of this species.

The misplacement of *Chasmone apiculata* as a synonym of *A. collinum* (Bentham

1844, Harvey 1862) is the result of the sessile cleistogamous fruits being mistaken for chasmogamous fruits. *A. collinum* is distinguished by its imbricate, subsessile leaves and solitary, subsessile chasmogamous flowers.

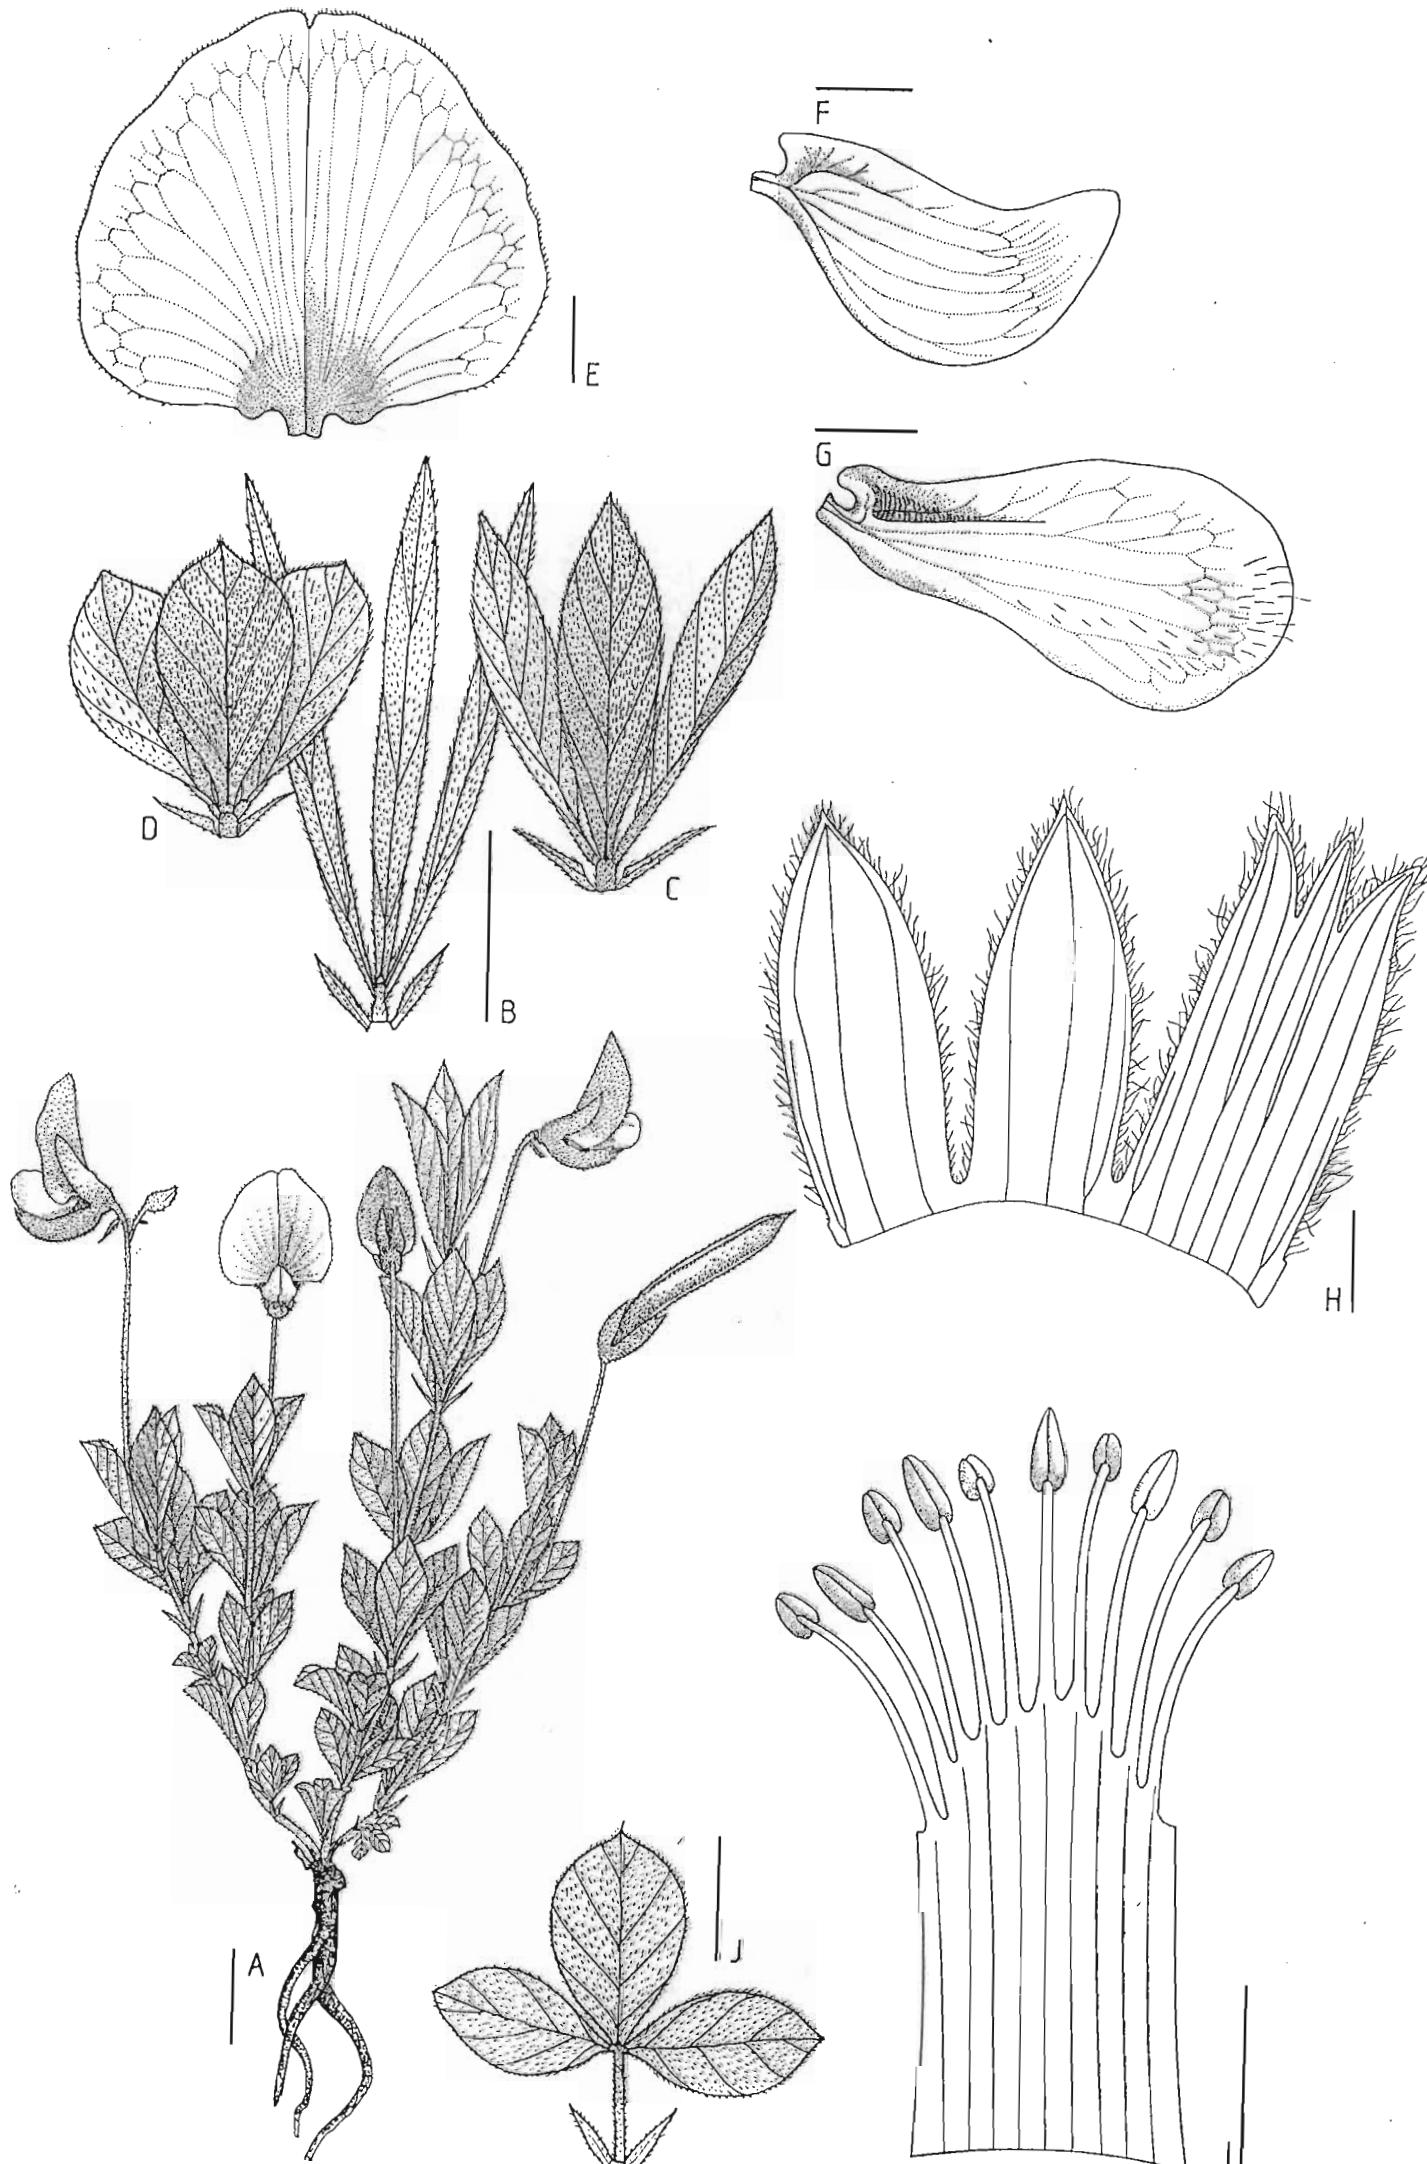

The species occurs in rocky grasslands of many vegetation types and across a range of altitudes from the Cape to southern Transvaal (Figure 70).

6355 (K!, lecto.; NH!, PRE!, SAM!, isolecto.).

Argyrolobium hirsuticaule Harms: 179 (1917). Type: Transkei, Zuurbergen, Schlechter 6571 (B†; BOL!, lecto. selected here).

Argyrolobium leptocladum Harms: 180 (1917). Type: Transkei, Clydesdale, Tyson 1256 pro parte (B†; BM!, icono.).

Argyrolobium thodei Harms: 184 (1917). Type: Orange Free State, Witsieshoek, Thode 20 (B†; BM!, icono.).

Lotononis magnistipulata Dümmer: 299 (1913). Type: South Africa, Faku's Territory (probably Transkei), Sutherland s.n. (K, holo.).

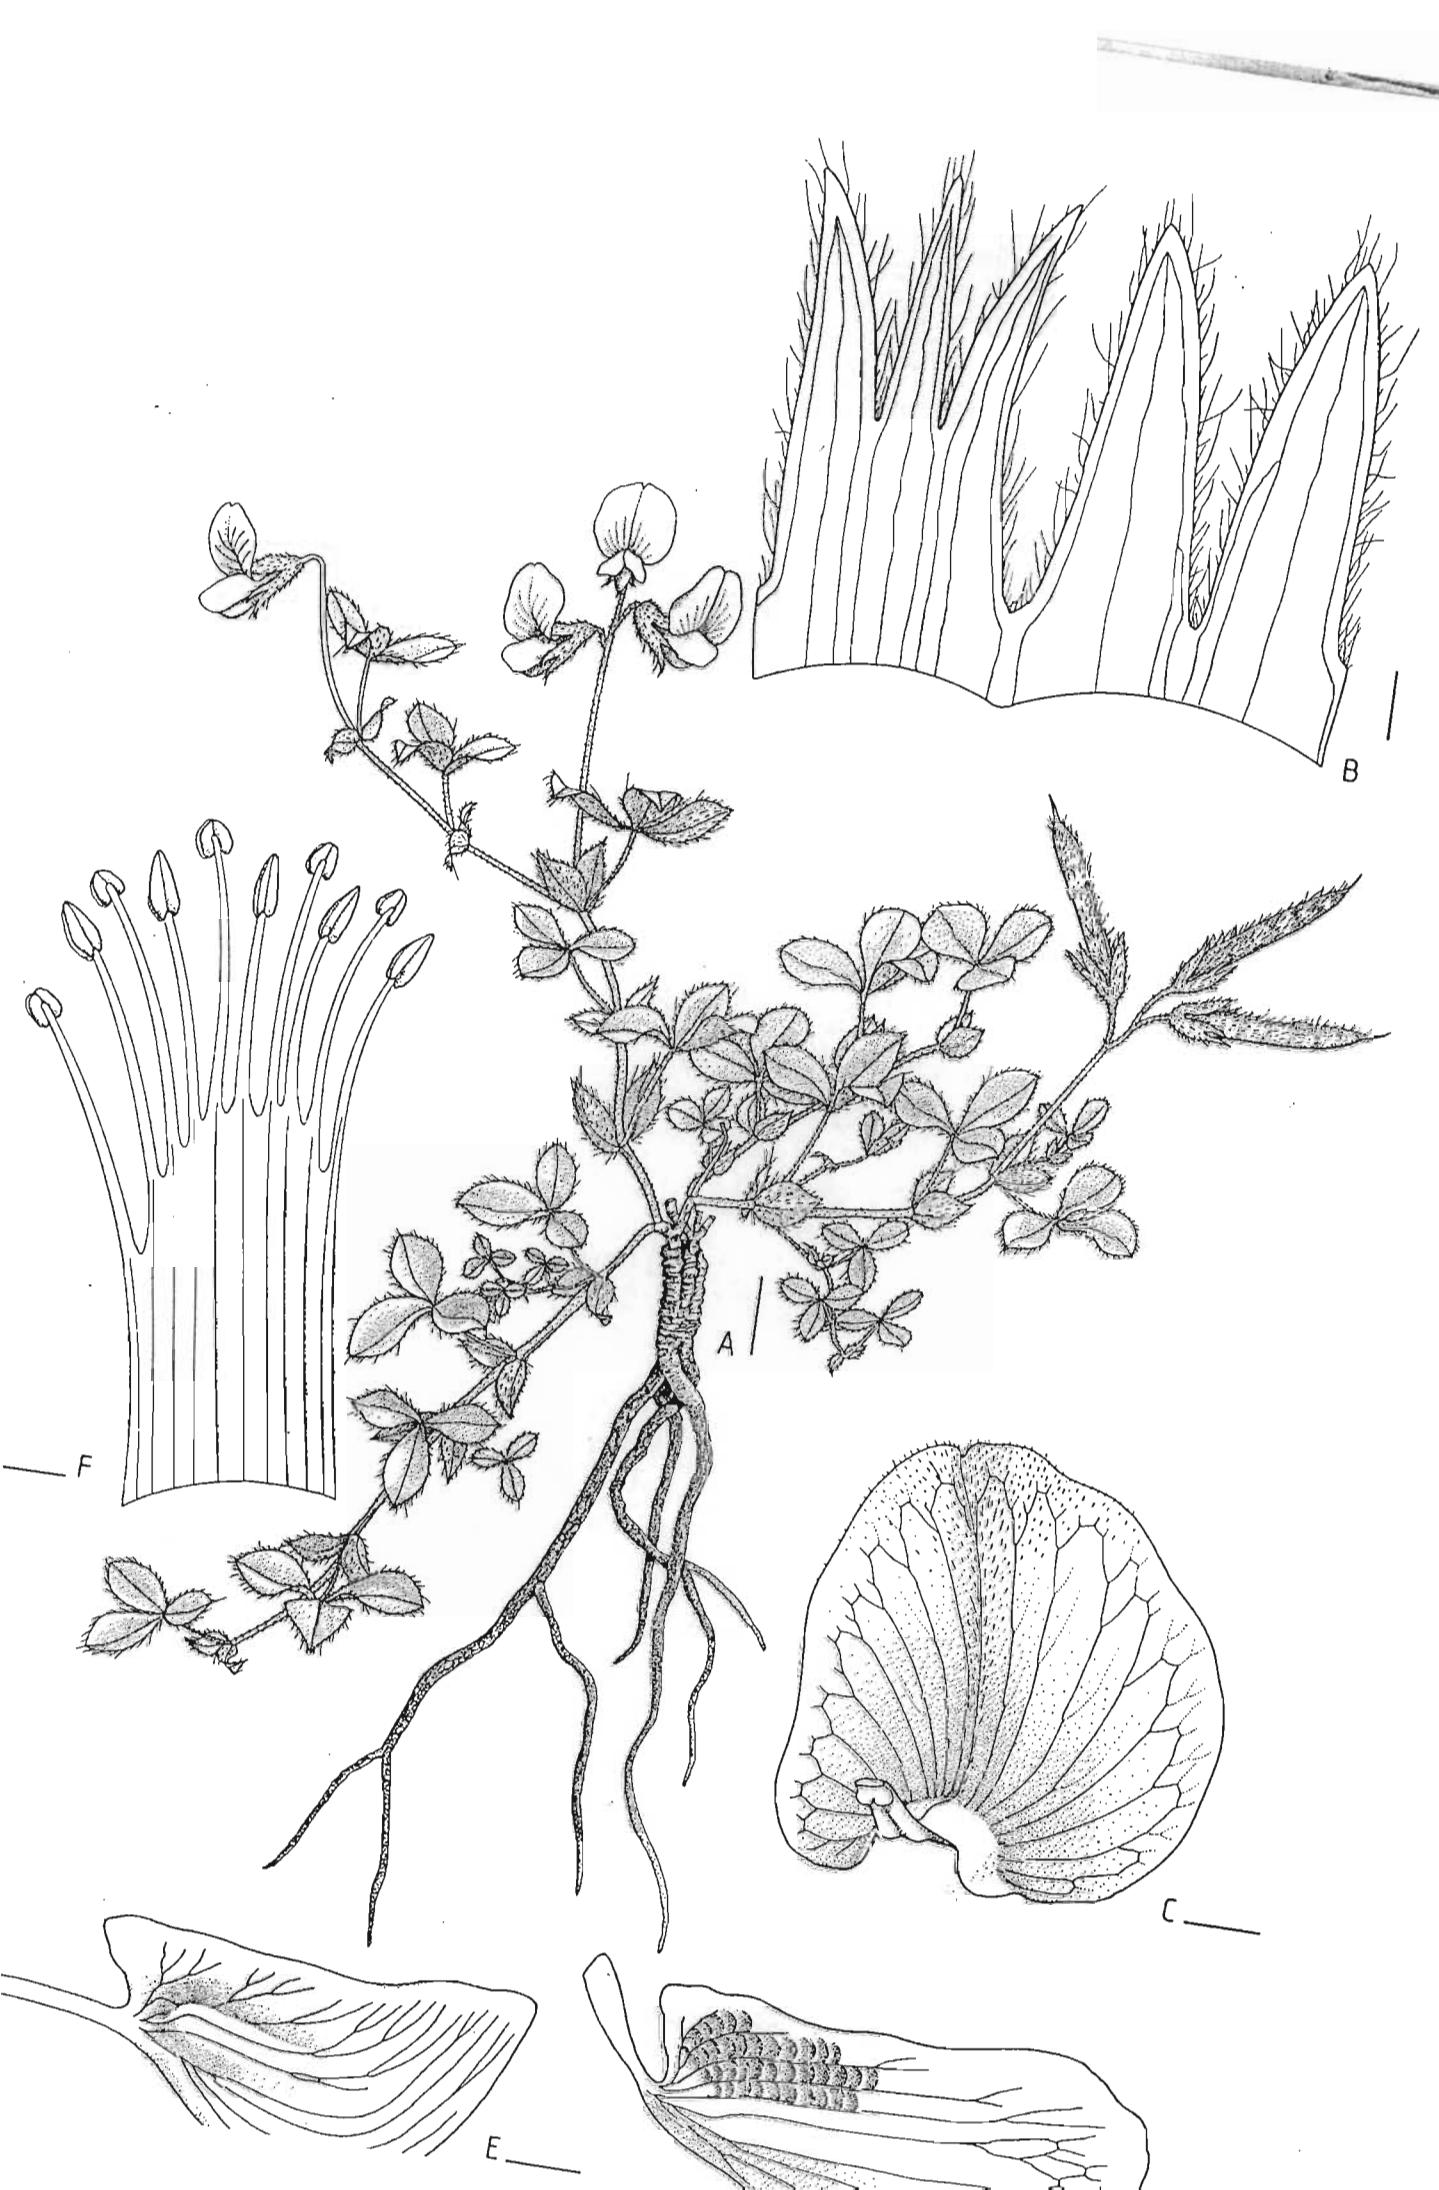

Herb, up to 0.45 m tall, becoming decumbent; stems weakly perennial, sericeous to pilose, becoming glabrous; roots ligneous, perennial. Leaves glabrous to sparsely pilose on both surfaces; leaflets narrowly ovate to sub-orbicular, 3--17 (-40) x 2--13 (-20) mm; petiole sericeous to pilose, 5--20 mm long; apex acute to rounded, mucronate; stipules foliaceous, narrowly ovate to broadly elliptical, 13--16 (-20) x 2--9 (-13) mm. Inflorescence pseudo-umbellate, 1--10 -flowered, initially terminal but becoming leaf-opposed; peduncle (5--) 15--45 (-65) mm long; bracts linear, 1.5--3 x 0.5--1 mm, bracteoles minute. Flowers dimorphic. Calyx sparsely pilose, deeply bilabiate; upper lobes 6--9 mm long, lower lip 7--9 mm long, lobes 3--4.5 x 1 mm. Corolla bright yellow fading to russet; standard suborbicular, 6--10 x 7--9.5 mm, adaxial surface sparingly sericeous, base cordate, claw 2--3 mm long; wings obovate, 6--8 x 3.5--4 mm, glabrous, with

lunate sculpturing in the upper basal and upper central zones, claw 2 mm long; keel cymbiform, 7--9 x 3.5--4 mm, glabrous, claw 2 mm long. *Stamens* monadelphous, split adaxially. *Ovary* narrowly oblong; 7--9 mm long; style 2--3 mm long. *Fruit* sparsely pilose, up to 35 x 3 mm. *Seed* suborbicular, laterally compressed, 2--2.5 x 1.8--2 mm, speckled dark brown, hilar rim raised.

This species displays considerable variation. The earliest collection of was made by Drège (n. 6629) and is housed at P. It bears the name *Chasmosyne pilosissima* E. Mey. but no description was traced. *A. lotoides* is the oldest published name predating the commonly used epithet *A. variopile* by nearly 50 years. The former description was published by Harvey in "Addenda and Corrigenda to the second volume" of Flora Capensis (1862) and may have been overlooked by subsequent researches.

A. hirsuticaule Harms was described from a Schlechter specimen collected at "Zuurbergen". This locality is in fact Zuurberg near Kokstad and not the south-eastern Cape locality.

The three names published by Harms (1917) were based on differences in vestiture and leaflet dimensions. These highly variable characters form a continuum and are thus unsuitable for delimiting species. The specimens from which *A. leptocladum* and *A. hirsuticaule* were described were destroyed at B but drawings of these

specimens are housed at BM (Edwards 1993a). The type of *A. leptocladum* is part of a mixed collection (Tyson 1256), unfortunately only specimens of *A. amplexicaule* remain from this gathering.³⁶

The homonym *A. lotoides* Bunge ex Trautv. was published in 1873, 11 years after Harvey's epithet, from material collected in Armenia.

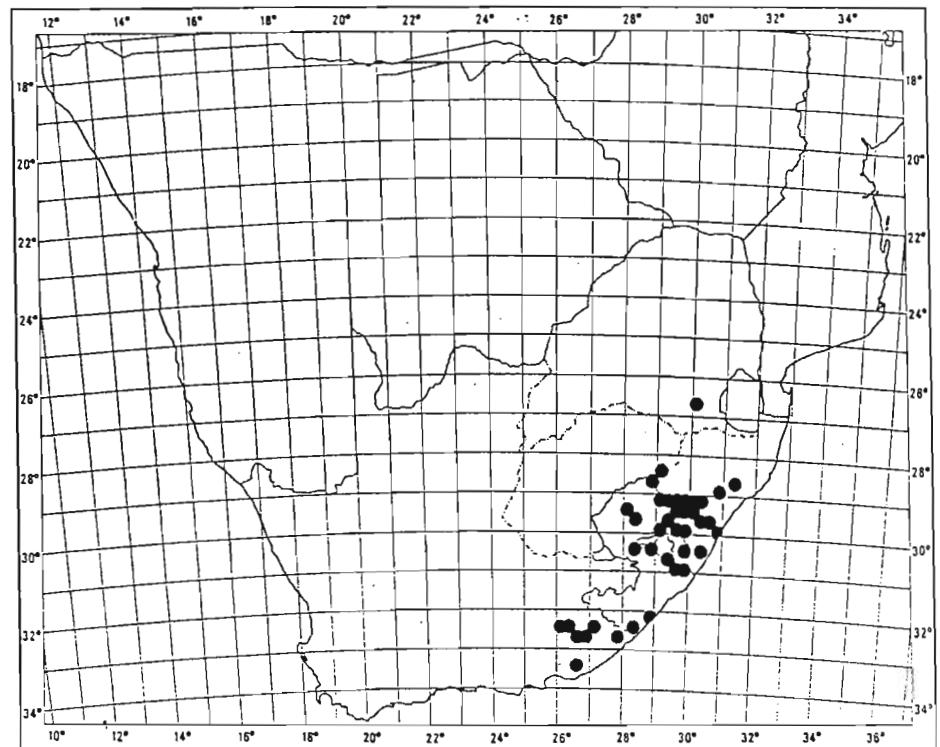

A. lotoides occurs at high altitude along the Drakensberg in the eastern Transvaal and Natal but at lower altitudes in the eastern Cape. Plants commonly occur in Highland and Dohne Sourveld and *Themeda-Festuca* Alpine Veld (Figure 79).

26. *Argyrolobium pauciflorum* Eckl. & Zeyh., Enum. Pl. Afr. Austr. 2: 186 (1836), non *A. pauciflorum* (Willd.) Haydek; Walp.: 507 (1839); Walp.: 631 (1843); Harv.: 74 (1862); Harms: 180-181 (1917); Burtt-Davy: 393 (1926). Type: eastern Cape, Zuurepoort, Stormberg, *Zeyher* s.n. (S!, neo. selected here). [Original type: eastern Cape, Stormberg near the Kei River source, *Ecklon & Zeyher* 1314 (B†)].

Argyrolobium pauciflorum var. *semiglabrum* Harv.: 74 (1862), *nom. nud.* *Argyrolobium biflorum* Eckl. & Zeyh.: 186 (1836); Benth.: 347 (1844). Type: Cape Province, Philipstown, Winterberg, *Ecklon & Zeyher* 1317 (S!, lecto. selected here).

Chasmone stricta E. Mey.: 75 (1836). Type: Cape, between Klipplaatrivier and Swartkei, *Drège* s.n. (BM!, lecto. selected here; G!, MO!, O!, P!, isolecto.).

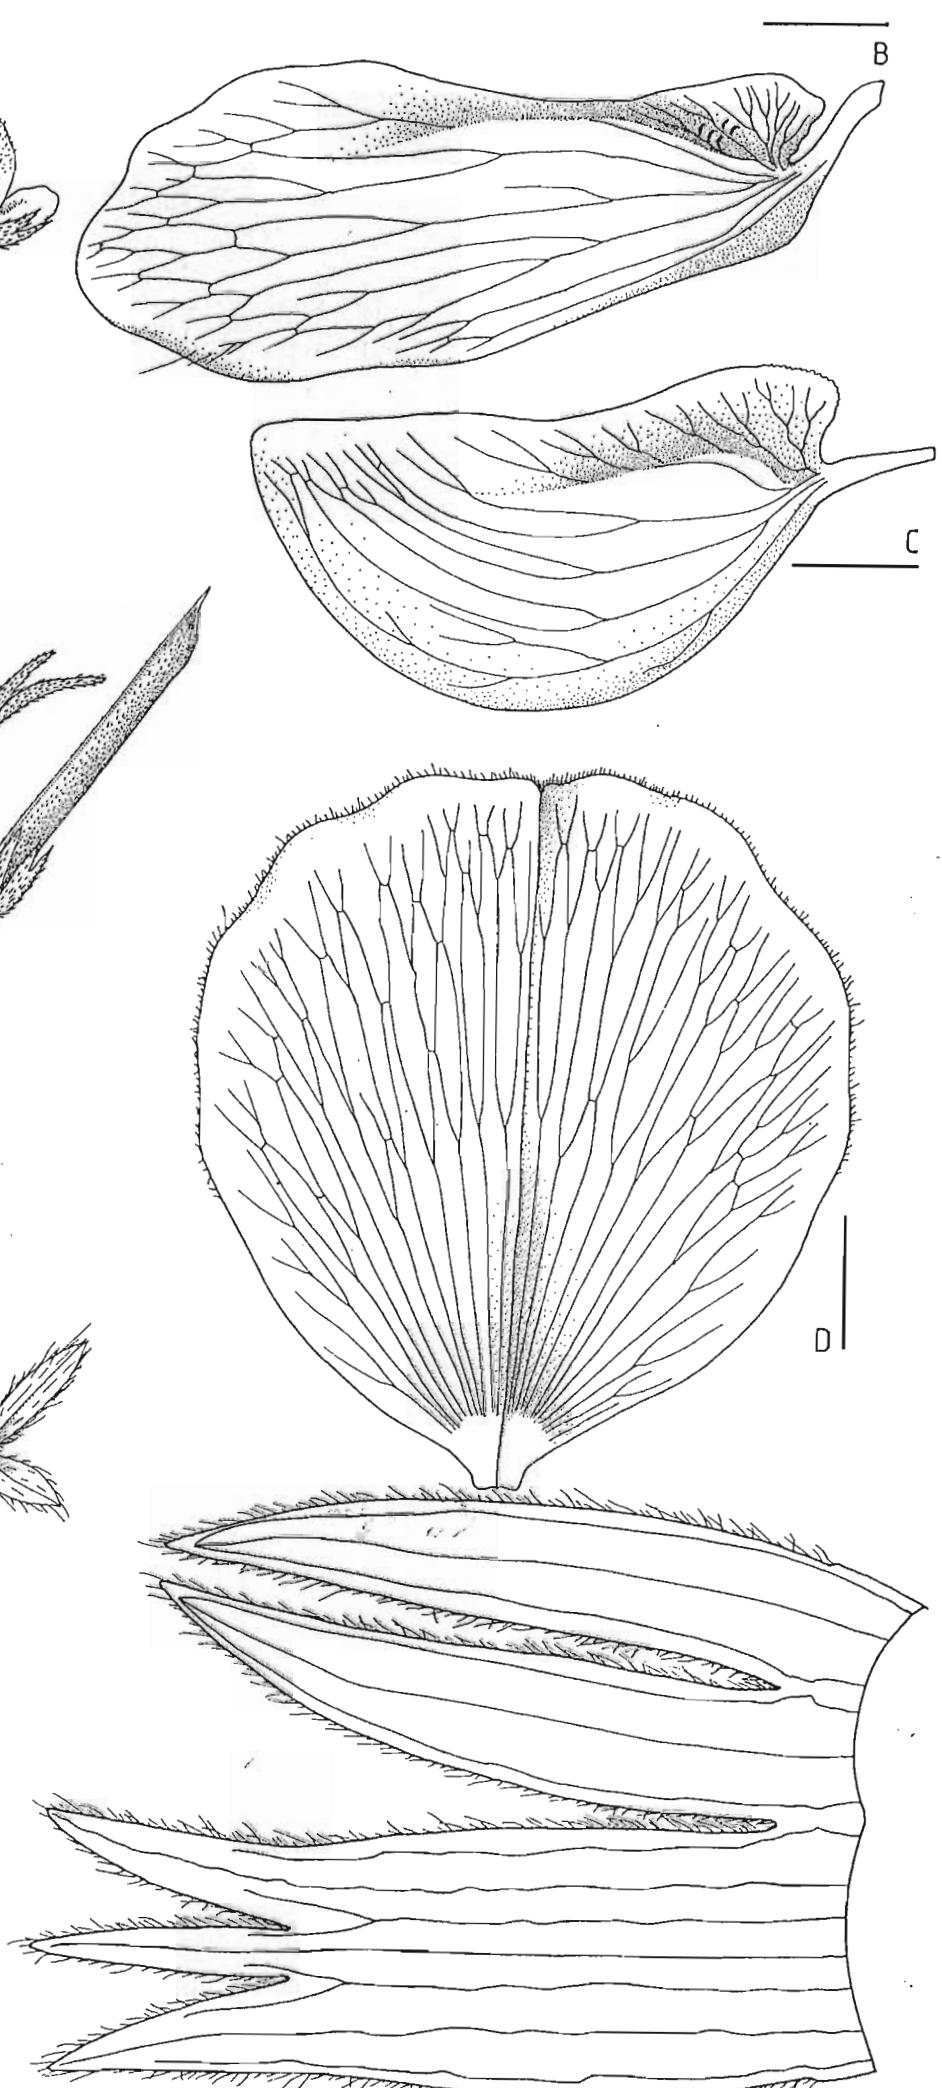

Argyrolobium strictum Steud.: 130 (1840); Benth.: 346 (1844). Type: as above.

Herb 0.1--0.2 m tall, erect or decumbent; stems weakly perennial, pilose; roots

ligneous, perennial. *Leaves* pilose on both surfaces; leaflets 13--26(--35) x 4--8(--12) mm, basal leaflets narrowly ovate to elliptic, upper leaflets lanceolate, conduplicate; petiole pilose, 10--30 mm long; apex acute to rounded, mucronate; stipules lanceolate, 5--12 x 1--2 mm. *Inflorescence* 1--2-flowered, initially terminal but becoming leaf-opposed; peduncle 15--70 mm long; bracts linear or setaceous 3--9 x 0.25--0.5 mm, bracteoles setaceous 1--3 x 0.25--0.5 mm. *Flowers* dimorphic. *Calyx* pilose, deeply bilabiate; upper lobes 10--12 mm long, upper sinus 8--10 mm, lower lip 11--14 mm long, lobes 3--4 mm long. *Corolla* bright yellow fading to russet; standard suborbicular, 11--17 x 9--13 mm, adaxial surface sericeous, base cordate, claw 1--2 mm long; wings oblong to obovate, 10--14 x 3.5--4 mm, sparingly sericeous, claw 1--2 mm long, with lunate-lamellate sculpturing in the upper basal and upper central zones; keel cymbiform, 9--11 x 4--5 mm, sometimes sparingly sericeous along the lower suture, claw 1--2 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 6--9 mm long; style 4--6 mm long. *Fruit* sparsely pilose, 30--60 x 4--6 mm. *Seed* suborbicular, laterally compressed, 2--3 mm, light to dark brown.

The homonym *A. pauciflorum* (Willd.) Hayek was published in 1926 for Asian material.

A. pauciflorum is allied to *A. campicola* and is distinguished by its smaller, free stipules and its long petioles. Considerable material of *A. molle* has been

misplaced under this species however the large stature of vegetative and reproductive parts, the prominent petioles and the lanceolate upper leaflets distinguish it.³⁷

The species occurs at high altitude, commonly in Highland and Dohne Sourveld (Figure 74).

Drège s.n. (BM, G, MO, O).

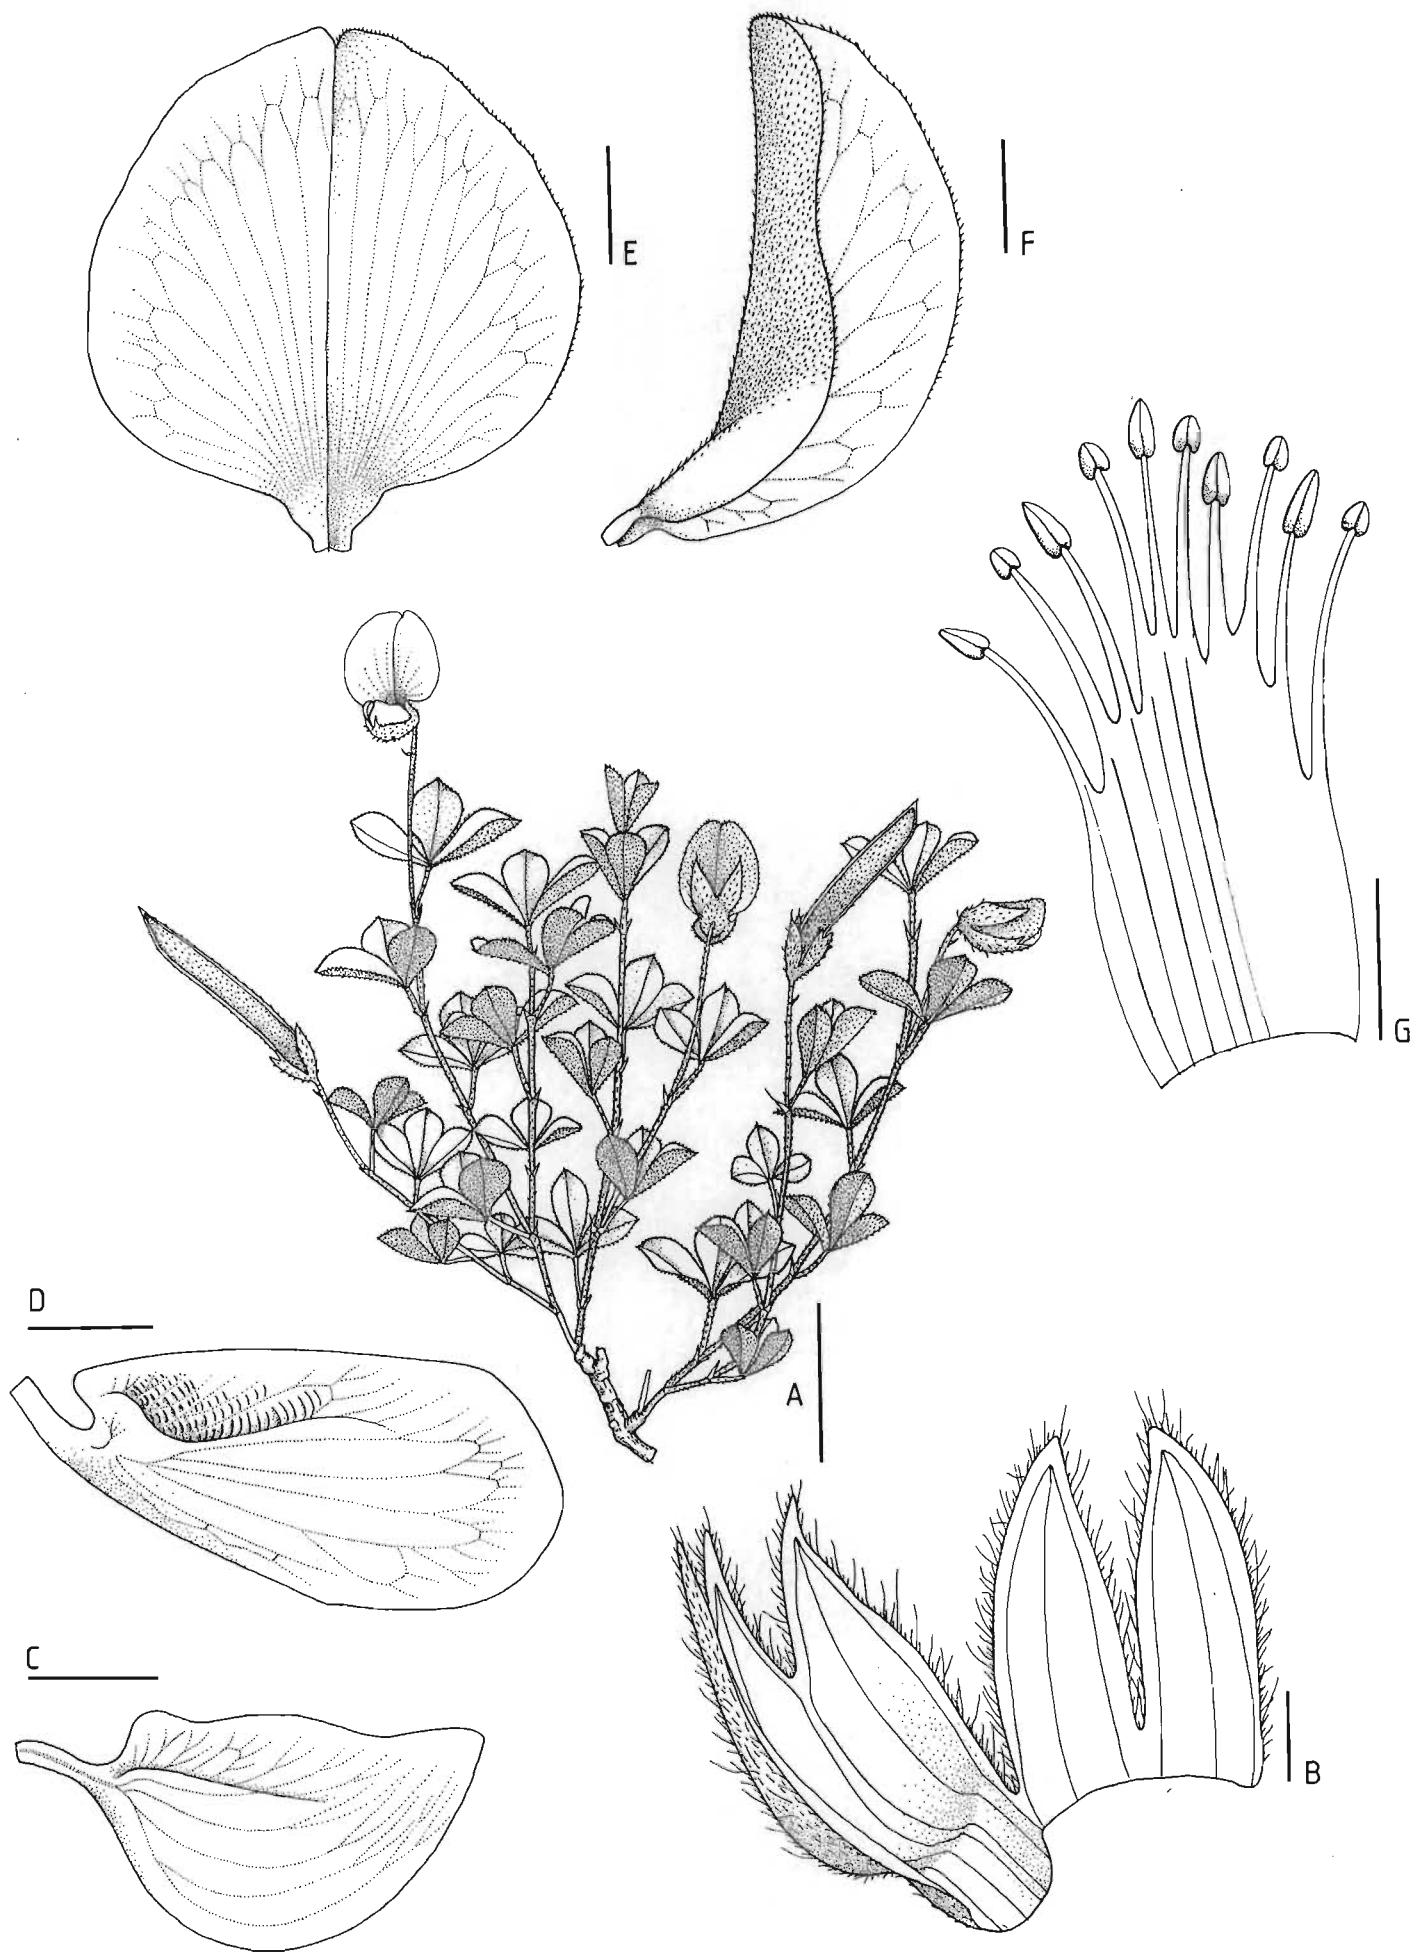

27. *Argyrolobium pumilum* Eckl. & Zeyh., Enum. Pl. Afr. Austr. 2: 185 (1836); Walp.: 508 (1839); Walp.: 632 (1843); Benth.: 346 (1844); Harv.: 75 (1862); Harms: 181 (1917). Type: Cape Province, Uitenhage, Van Stadensrivierberge, *Ecklon & Zeyher s.n.* (SAM!, lecto. selected here; C!, P!, PRE!, S!, isolecto.).

Argyrolobium venustum Eckl. & Zeyh.: 185 (1836). Type: Uitenhage, Addow (Addo), *Ecklon & Zeyher s.n.* (O!, lecto. selected here; C!, GRA!, MO!, S!, isolecto.).

Chasmone pusilla E. Mey.: 600 (1836). Type: not traced.

Galega sericea Thunb.: 134 (1794), pro parte. Type: Cape Province, *Thunberg s.n. sub THUNB-UPS 17396* (UPS!).

Herbaceous perennial, shortly erect or procumbent, usually well branched, stems densely sericeous, perennial. Leaves monomorphic, densely sericeous abaxially and marginally, adaxial surface glabrous; leaflets, broadly obovate to oval, (5--)7--15(--20) x (3--)4--10(--12) mm, central vein prominent below and grooved above; petiole densely sericeous, often longer on lower leaves, 2--10(--21) mm long; apex rounded, apiculate; stipules linear-lanceolate to subulate, often reflexed, 0.5--4 x 0.25--0.5(--1) mm, apex acute. Inflorescence 1(--2)-flowered, terminal but becoming leaf-opposed; peduncle 5--20(--40) mm long; bracts linear, 1--2.5 x

0.25--0.5 mm; bracteoles, setaceous or absent. *Flowers* dimorphic. *Calyx* sericeous, deeply bilabiate; upper lip 7--9 mm long, upper sinus 3.5--6 mm, lower lip 8--11 mm long, lobes 2--3.5 mm long. *Corolla* bright yellow fading to russet; standard suborbicular, 8--13.5 x 8--14 mm, adaxial surface sericeous, base obtuse, claw 1 mm long; wings oblong to obovate, 7--10 mm, sculpturing in the upper basal and upper central zones, glabrous, claw 1--1.5 mm long; keel cymbiform 7--9.5 x 3--4 mm, glabrous, claw 1--2 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 4--6 mm long; style 3--4 mm long. *Fruit* sparsely sericeous, slightly inflated, 20--45 x 3.5--4 mm. *Seed* suborbicular, laterally compressed, 1.5--2 x 1.5--2.5 mm, red-brown to dark brown, sometimes speckled.

A. pumilum is a distinctive species with dark green, disolorous leaflets lined by a silver margin, plants are common on rock outcrops and areas of baked earth. The species is sometimes confused with decumbent plants of *A. molle* which are sympatric in the eastern Cape. *A. molle* is distinguished by its larger, narrower (often conduplicate) leaflets, short petioles overtopped by stipules, prominent leaf venation and inflorescences which usually bear two or more flowers. The species is common in False Macchia grassveld (Figure 83). ³⁸

Incorrectly as *Chasmone sessilifolia*, Drège: 46 & 51 (1844).

Argyrolobium summomontanum Hilliard & Burtt: 308 (1983), *synon. nov.*

Type: Lesotho-Natal Border, hill slopes behind escarpment south of Sani Pass,

Hilliard & Burtt 8871 (E!, holo.; NU!, iso.).

Herbaceous perennial, erect, sparingly branched, stems densely sericeous to shortly pilose, annual to perennial, often stoloniferous. *Leaves* monomorphic, densely sericeous abaxially and marginally, adaxial surface sparsely pilose to densely sericeous; leaflets, obovate to oblanceolate, often conduplicate, 4–9 x 2–5 mm; petiole 1–3 mm long; apex rounded, apiculate to recurvomucronate; stipules broadly, obliquely ovate, 4–10 x 3–7 mm. *Inflorescence* 1-flowered, sessile, leaf-opposed; bracts lanceolate, 2–5 x 1–2 mm; bracteoles, linear-lanceolate 2–4 x 0.5 mm. *Flowers* dimorphic. *Calyx* sericeous, deeply bilabiate; upper lip 7–10 mm long, upper sinus 5–7 mm, lower lip 7–10 mm long, lobes 3–5 mm long. *Corolla* bright yellow fading to russet; standard suborbicular, 9–12 x (8–)10–12 mm, adaxial surface sericeous, base obtuse, claw 1–2 mm long; wings oblong to obovate, 9–11 x 4–5 mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, glabrous to sparsely sericeous in the lower distal zone, claw 1.5–2 mm long; keel cymbiform 8–11 x 4–5 mm, glabrous, claw 1–2 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 4–5 mm long; style 3–4 mm long. *Fruit* densely sericeous to pilose, inflated, 17–30 x 4–

5.5 mm. Seed reniform, laterally compressed, 1.5–2 mm, red-brown to dark brown. ³⁹

Hilliard and Burtt (1983) described *A. summomontanum* without viewing material of *A. candicans* although they suggest an alliance between these species. The diagnostic characters they outlined refer to habit, vestiture and leaflet shape. These are variable in *A. candicans* and do not support the continued recognition of *A. summomontanum*.

Extremes of variation relate to the wide altitudinal range of *A. candicans*. The species occur mainly in Highland and Dohne Sourveld and *Themeda-Festuca* Alpine Veld but extends into Coastal Thornveld. This distributional pattern is similar to *A. stipulaceum*, a close ally (Figure 79). Coastal specimens (*Flanagan* 1343) are larger and have weakly conduplicate, broadly obovate leaflets while specimens collected at high altitude are smaller, often with strongly conduplicate leaflets.

Chasmone verticillata E. Mey.: 72 (1836). Types: eastern Cape, Katberg *Drège s.n.* (BM!, lecto. selected here; K!, P!, S!, isosyn.); between Kei and Basche, *Drège s.n.* (P!, syn.).

Herbaceous perennial, erect, sparingly branched, stems densely sericeous to pilose, weakly perennial. *Leaves* monomorphic, densely sericeous abaxially and marginally, adaxial surface pilose to sericeous; leaflets, obovate to oblanceolate, (8--)10--35(--40) x (2--)4--13(--16) mm, sometimes conduplicate; petiole (0--)1--7 mm long; apex rounded, apiculate; stipules broadly, obliquely ovate, 9--34 x 4--17(--20) mm. *Inflorescence* 1--6-flowered, usually congested, terminal but becoming leaf-opposed; peduncle 3--57 mm long; bracts linear to narrowly oblanceolate, 4--8 x 0.5--1 mm; bracteoles, setaceous or absent, 0--3 x 0--0.25. *Flowers* dimorphic. *Calyx* sericeous, deeply bilabiate; upper lip 9--12 mm long, upper sinus 6--9 mm, lower lip 10--15 mm long, lobes 4--8 mm long. *Corolla* bright yellow fading to russet; standard suborbicular, 13--16 x 11--15 mm, adaxial surface sericeous, base obtuse, claw 1 mm long; wings oblong to obovate, 11--15

mm, with ill-defined sculpturing in the upper basal and upper central zones, glabrous to sparsely sericeous in the lower distal zone, claw 1--1.5 mm long; keel cymbiform 9--12 x 4--5 mm, glabrous, claw 1--2 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 5--7 mm long; style 3--4 mm long. *Fruit* densely sericeous to pilose, inflated, 27--39 x 8--10 mm. *Seed* reniform, laterally compressed, 2--2.5 x 2--2.5 mm, red-brown to dark brown.

40

A. stipulaceum is variable in size but consistent in morphology. It is distinguished by its very large stipules and inflated fruits. The close ally *A. candicans* differs in its diminutive stature, smaller, solitary, subsessile chasmogamous flowers (rarely chasmogamous flowers are subsessile in *A. stipulaceum*) and short internodes. When identifying fruiting specimens calyx size must be checked because cleistogamous flowers of *A. stipulaceum* are always subsessile. *A. stipulaceum* occurs in grasslands across a wide altitudinal range. Specimens have been collected mainly in Coastal Thornveld, Dohne and Highland Sourveld and *Themeda-Festuca* Alpine Veld (Figure 79).

Without precise locality: Natal, *Gerrard & McKen 1761* (TCD); *Gueinzius s.n.*

30. *Argyrolobium velutinum* Eckl. & Zeyh., *Enum. Pl. Afr. Austr.* 2: 186 (1836); Walp.: 507 (1839); Walp.: 631 (1843); Benth.: 344 (1844); Harv.: 71 (1862); Harms: 182 (1917). Type: Cape, near Simonstown, *Ecklon & Zeyher* 1313 (P!, lecto. selected here; GRA!, S!, SAM!, isolecto.).

Suffrutex up to 0.1--0.5 m tall, decumbent or scandent sometimes erect; stems sparingly branched, weakly perennial, sericeous to densely villous, becoming glabrous; roots ligneous, perennial. *Leaves* sericeous to velutinous; leaflets, 9--45 x 3--14 mm, often broadly obovate below, narrowly obovate to oblanceolate above, often conduplicate, apex acute to rounded, mucronate; petiole sericeous to velutinous, 9--20 mm long; stipules, ovate to lanceolate, 2--10 x 1--4 mm. *Inflorescence*, 1--5-flowered, terminal but becoming leaf-opposed; peduncle 0--6 mm long; bracts linear, 2--5 x 0.5--1 mm, bracteoles linear or setaceous. *Calyx* villous, deeply bilabiate; upper lobes 10--12 mm long, upper sinus 8--10 mm deep, lower lip 10--13 mm long, lobes 3--4 mm long. *Corolla* bright yellow

A

B

C

D

E

fading to russet; standard suborbicular, 10--14 x 9--12 mm, adaxial surface densely sericeous, base rounded, claw 1 mm long; wings oblong to obovate, 10--13 x 4--5 mm, distally sericeous, with lunate-lamellate sculpturing in the upper basal and zone, claw 1--2 mm long; keel cymbiform, 9--10 x 4--5 mm, sparingly sericeous along the lower suture, claw 1--2 mm long. *Stamens* monadelphous sheath completely fused above. *Ovary* narrowly oblong, 5--6 mm long; style 3--4 mm long. *Fruit* sericeous, inflated, 24--35 x 6--7 mm. *Seed* suborbicular, slightly compressed, 2--3 mm in diameter, dark red-brown. ⁴¹

Argyrolobium velutinum produces chasmogamous flowers sparingly and is therefore seldom collected. Sessile, multi-flowered inflorescences also occur in *A. filiforme* but its small sature and compressed pods distinguish it. The inflated fruits of *A. velutinum* are unique among species from the Cape West Coast. The species grows in Macchia and Strandveld vegetation (Figure 85).

Chasmone argentea (Jacq.) E. Mey. var. *pilosa* E. Mey.: 75 (1836). Type: eastern Cape, between Gekau and Basche; Modderfontein near Brakrivier; Nieuwveld, near Gansefontein; (G!, MO!, W!; syn. without specified localities).

Argyrolobium pumilum Eckl. & Zeyh. var. *pilosum* (E. Mey.) Harv.: 74 (1862), *synon. nov.* Type: as above.

Dichilus obovatus E. Mey.: 151 (1832), *synon. nov.* Type: eastern Cape, Uitenhage, *Ecklon s.n.* (S!, lecto. selected here).

Argyrolobium obovatum (E. Mey.) Eckl. & Zeyh.: 185 (1836); Walp.: 508

(1839). Type: as above.

Argyrolobium collinum Eckl. & Zeyh. var. *seminudum* Harv.: 72 (1862),
synon. nov. Type: eastern Cape, Uitenhage, Zoutpanshoogte, *Zeyher* 3201 (S!,
lecto. selected here; G!, P! isolecto.).

Argyrolobium collinum Eckl. & Zeyh. var. *angustatum* Harv.: 72 (1862),
synon. nov. Type: eastern Cape, Uitenhage, Swellendam, near Gouritzrivier,
Ecklon & Zeyher 1303 (S!, lecto. selected here).

Shrub, well branched, stems densely sericeous, perennial. *Leaves* weakly dimorphic, sericeous to pilose abaxially and marginally, adaxial surface glabrous to sparsely sericeous; leaflets, broadly obovate to obovate, 5–16 x 3–6 mm, central vein prominent below and grooved above; petiole densely sericeous to pilose, longer on lower leaves, 2–11(–16) mm long; apex rounded, apiculate; stipules subulate, sometimes patent or reflexed, 2–3 x 0.25–0.5 mm, apex acute. *Inflorescence* 1(–2)-flowered, terminal but becoming leaf-opposed; peduncle 1–2 (–40) mm long; bracts linear, to setaceous, 1–1.5 x 0.25 mm; bracteoles, setaceous or absent. *Flowers* dimorphic. *Calyx* sericeous, deeply bilabiate; upper lip 7–9 mm long, upper sinus 3–5 mm, lower lip 8–9 mm long, lobes 2–3 mm long. *Corolla* bright yellow fading to russet; standard broadly obovate, 9–11 x 6–9 mm, adaxial surface sericeous, base cuneate, claw 1–1.5 mm long; wings narrowly obovate, 8–9 x 3–3.5 mm, with lunate-lamellate sculpturing in the upper basal and upper central zones, distally sericeous, claw 1–1.5 mm long; keel

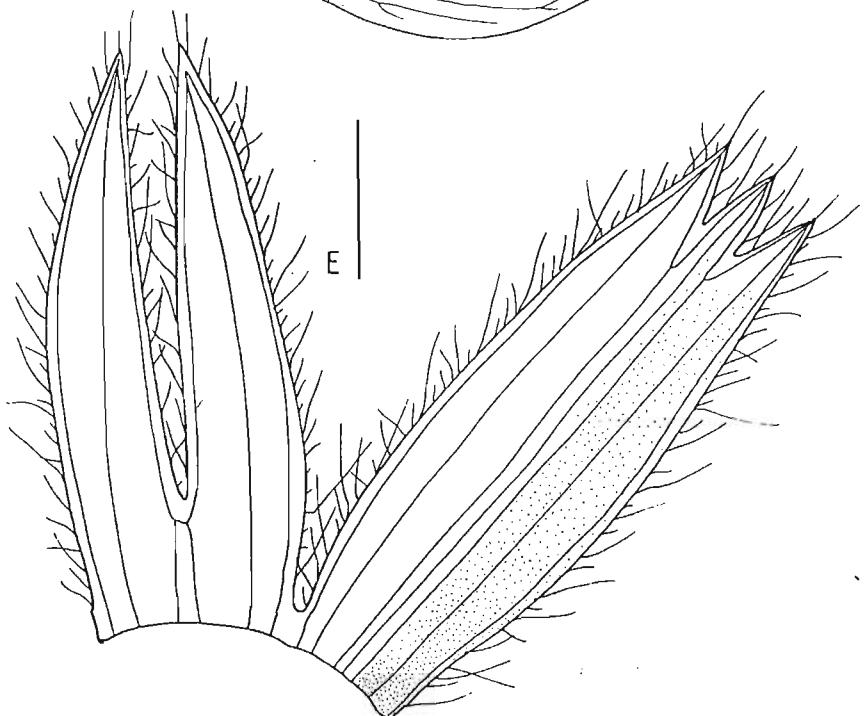

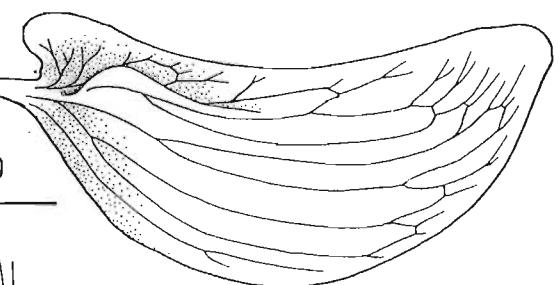

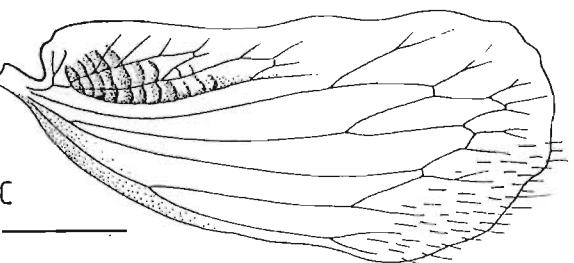

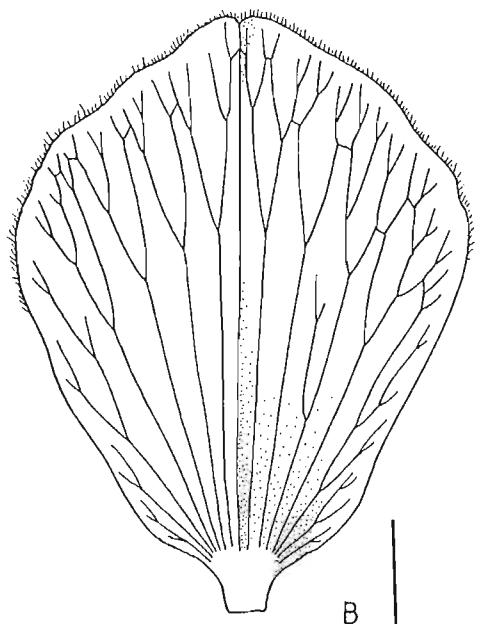

cymbiform 8.5–9 x 4 mm, glabrous, claw 1.5–2 mm long. *Stamens* monadelphous, sheath fused adaxially. *Ovary* narrowly oblong, 4–6 mm long; style 4–5 mm long. *Fruit* sparsely sericeous, slightly inflated, 20–40 x 3.5–4 mm. *Seed* suborbicular, 1.5–2 x 1.5–2.5 mm, light to dark brown.

This shrubby species occurs in dry vegetation of the interior (Figure 91) and is characterised by its densely sericeous stems and petioles. New growth is occasionally densely pilose.

A. argenteum was reduced to synonymy with *A. collinum* (Harvey 1862) due to its frequently subsessile, solitary flowers. However its lax, shrubby stature, sparser indumentum and pronounced petioles clearly separate *A. argenteum*. Occasionally its flowers are borne atop elongate peduncles but in many specimens the inflorescence appears to be pedunculate due to the delayed maturation of the terminal leaf which opposes the flowers. Sometimes up to three flowers are borne per node which is reminiscent of *A. filiforme*. The species has also been confused with *A. pumilum* but has smaller, subsessile flowers, narrower leaflets and is an erect shrub.

42

32. *Argyrolobium petiolare* (E. Mey.) Walp., Rep. 1: 632 (1843); Harv.: 72 (1862). Type: Cape Province, Kamiesberg, hills near Uitkomst, *Drège s.n.* (P!, lecto. selected here; G!, K!, MO!, O!, S!, W!, isolecto.).

Chasmone petiolaris E. Mey.: 75 (1836). Type: as above.

Shrubs 0.3--0.5 m tall, rigidly erect, well branched, stems shortly velutinous, becoming glabrous. Leaves shortly sericeous; leaflets narrowly oblong to oblong, 6--20 x 3--11 mm, often conduplicate, apex rounded or recurvomucronate, apiculate; petiole up to 30 mm long, adaxially canaliculate; stipules 0.8--1.5 x 0.5 mm, subulate. Inflorescence 1(--2)-flowered, leaf-opposed; peduncle 0--4 mm

Figure 88

Argyrolobium argenteum. A. Flowering branch (bar = 2 mm); B. standard, abaxial surface (bar = 2 mm); C. wing (bar = 2 mm); D. keel (bar = 2 mm); E. calyx, inner surface (bar = 2 mm). Voucher: Acocks 20077.

long; bracts narrowly oblong, 2–3 x 0.5 mm; bracteoles narrowly oblong, 2 x 0.5 mm. *Calyx* velutinous, deeply bilabiate; upper lobes 9–11 mm long, upper sinus 8.5–9 mm deep, lower lip 11–13 mm long, shallowly cymbiform, lobes acute, 1.5–2 mm long. *Corolla* yellow; standard suborbicular, 15–17 x 15–18 mm, adaxial surface sparingly sericeous, claw 1–2 mm long; wings oblong, 15.5–18 x 5–6 mm, glabrous, sculpturing lunate-lamellate, in the upper basal and central zones, claw 1–2 mm long; keel bluntly cymbiform, 13–14 x 5–6 mm, claw 2 mm long. *Stamens* monadelphous, sheath completely fused above. *Ovary* narrowly oblong, 9–11 mm long; style 4–6 mm long. *Fruit* velutinous, 45–60 x 7–8 mm. *Seed* suborbicular, 2.75–3 mm in diameter, dark brown.

A. petiolare is endemic to the Kamiesberg where it grows in Mountain Renosterbosveld (Figure 91). It is distinctive within the section due to its shrubby habit and sessile flowers.

2918 (Gamoep): Koperberg, (--CA), Pillans 5667 (BOL). 3017 (Hondekloofbaai): "Brackdamm" Kamieskroon, (--BB), Schlechter 11107 (BM, BOL, E, G, MO, PRE, W). 3018 (Kamiesberg): Uitkomst, (--CA), Drège 3299 (G, K, MO, O, P, S, W); Garies, (--CA), Caporn s.n. (BOL).⁴³

Figure 89

Argyrolobium petiolare. A. flowering branch (bar = mm); B. standard, adaxial surface (bar = 2 mm); C. calyx (bar = 2 mm); D. leaf (bar = 5 mm); E. keel (bar = 2 mm); F. wing (bar = 2 mm). Voucher: Schlechter 11107.

33. **Argyrolobium pachyphyllum** Schltr. in Engl. Jahrb. 24: 441 (1898). Type: Elim, on grassy hills Schlechter 7724 (K!, lecto. selected here; BOL!, BM!, E!, G!, MO!, S!, W!, isolecto.).

Dwarf shrub 100–250 mm tall, forming clumps; stems well branched, perennial, sericeous to shortly villose, becoming glabrous. *Leaves* pilose to shortly villose below, glabrous above; leaflets 8–15 x 5–8 mm, elliptic to obovate, strongly conduplicate, arcuate, apex rounded, apiculate; petiole 3(–5) mm long, adaxially canaliculate; stipules 0.5–2 x 0.25–0.5 mm, subulate. *Inflorescence* 1 (–2)-flowered, terminal, becoming leaf-opposed; peduncle 2–7 mm long; bracts 1–1.5 x 0.5 mm, linear; bracteoles 0.75 x 0.25 mm, linear. *Calyx* sparsely sericeous to shortly villose, deeply bilabiate; upper lobes 8–11 mm long, upper sinus 7–10 mm deep, lower lip 12–14 mm long, lobes acute, 2.5–4 mm long. *Corolla* yellow; standard suborbicular, 13–18 x 10–16 mm, adaxial surface sericeous, claw 2–3 mm long; wings obovate, 10–14 x 4.5–6 mm, sculpturing in the upper basal zone, claw 1–2 mm long; keel cymbiform, 9–13 x 4–6 mm, claw 1 mm long, lower margin sparsely hairy. *Stamens* monadelphous, sheath completely fused above. *Ovary* narrowly oblong, 7–9 mm long; style 3–4 mm long. *Fruit* not seen. *Seed* not seen.

Schlechter (1898) suggested an alliance between *A. pachyphyllum* and *A. collinum* which both produce solitary (occasionally two) flowers atop abbreviated peduncles however in *A. collinum* the peduncles are barely visible. The young stems of *A.*

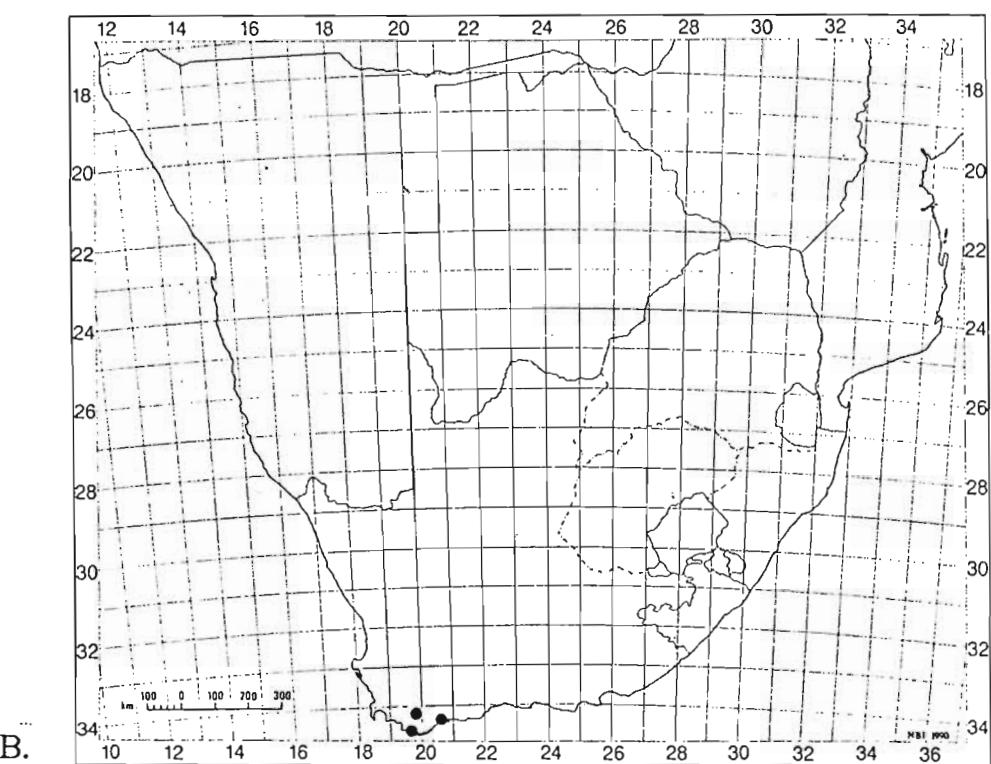

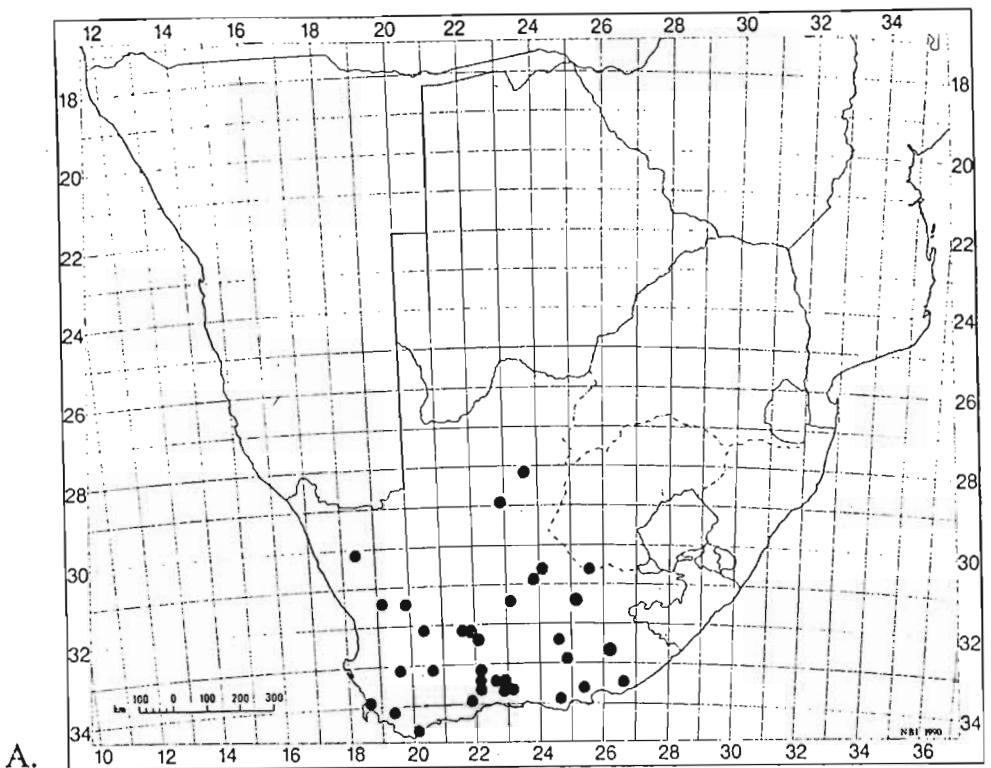

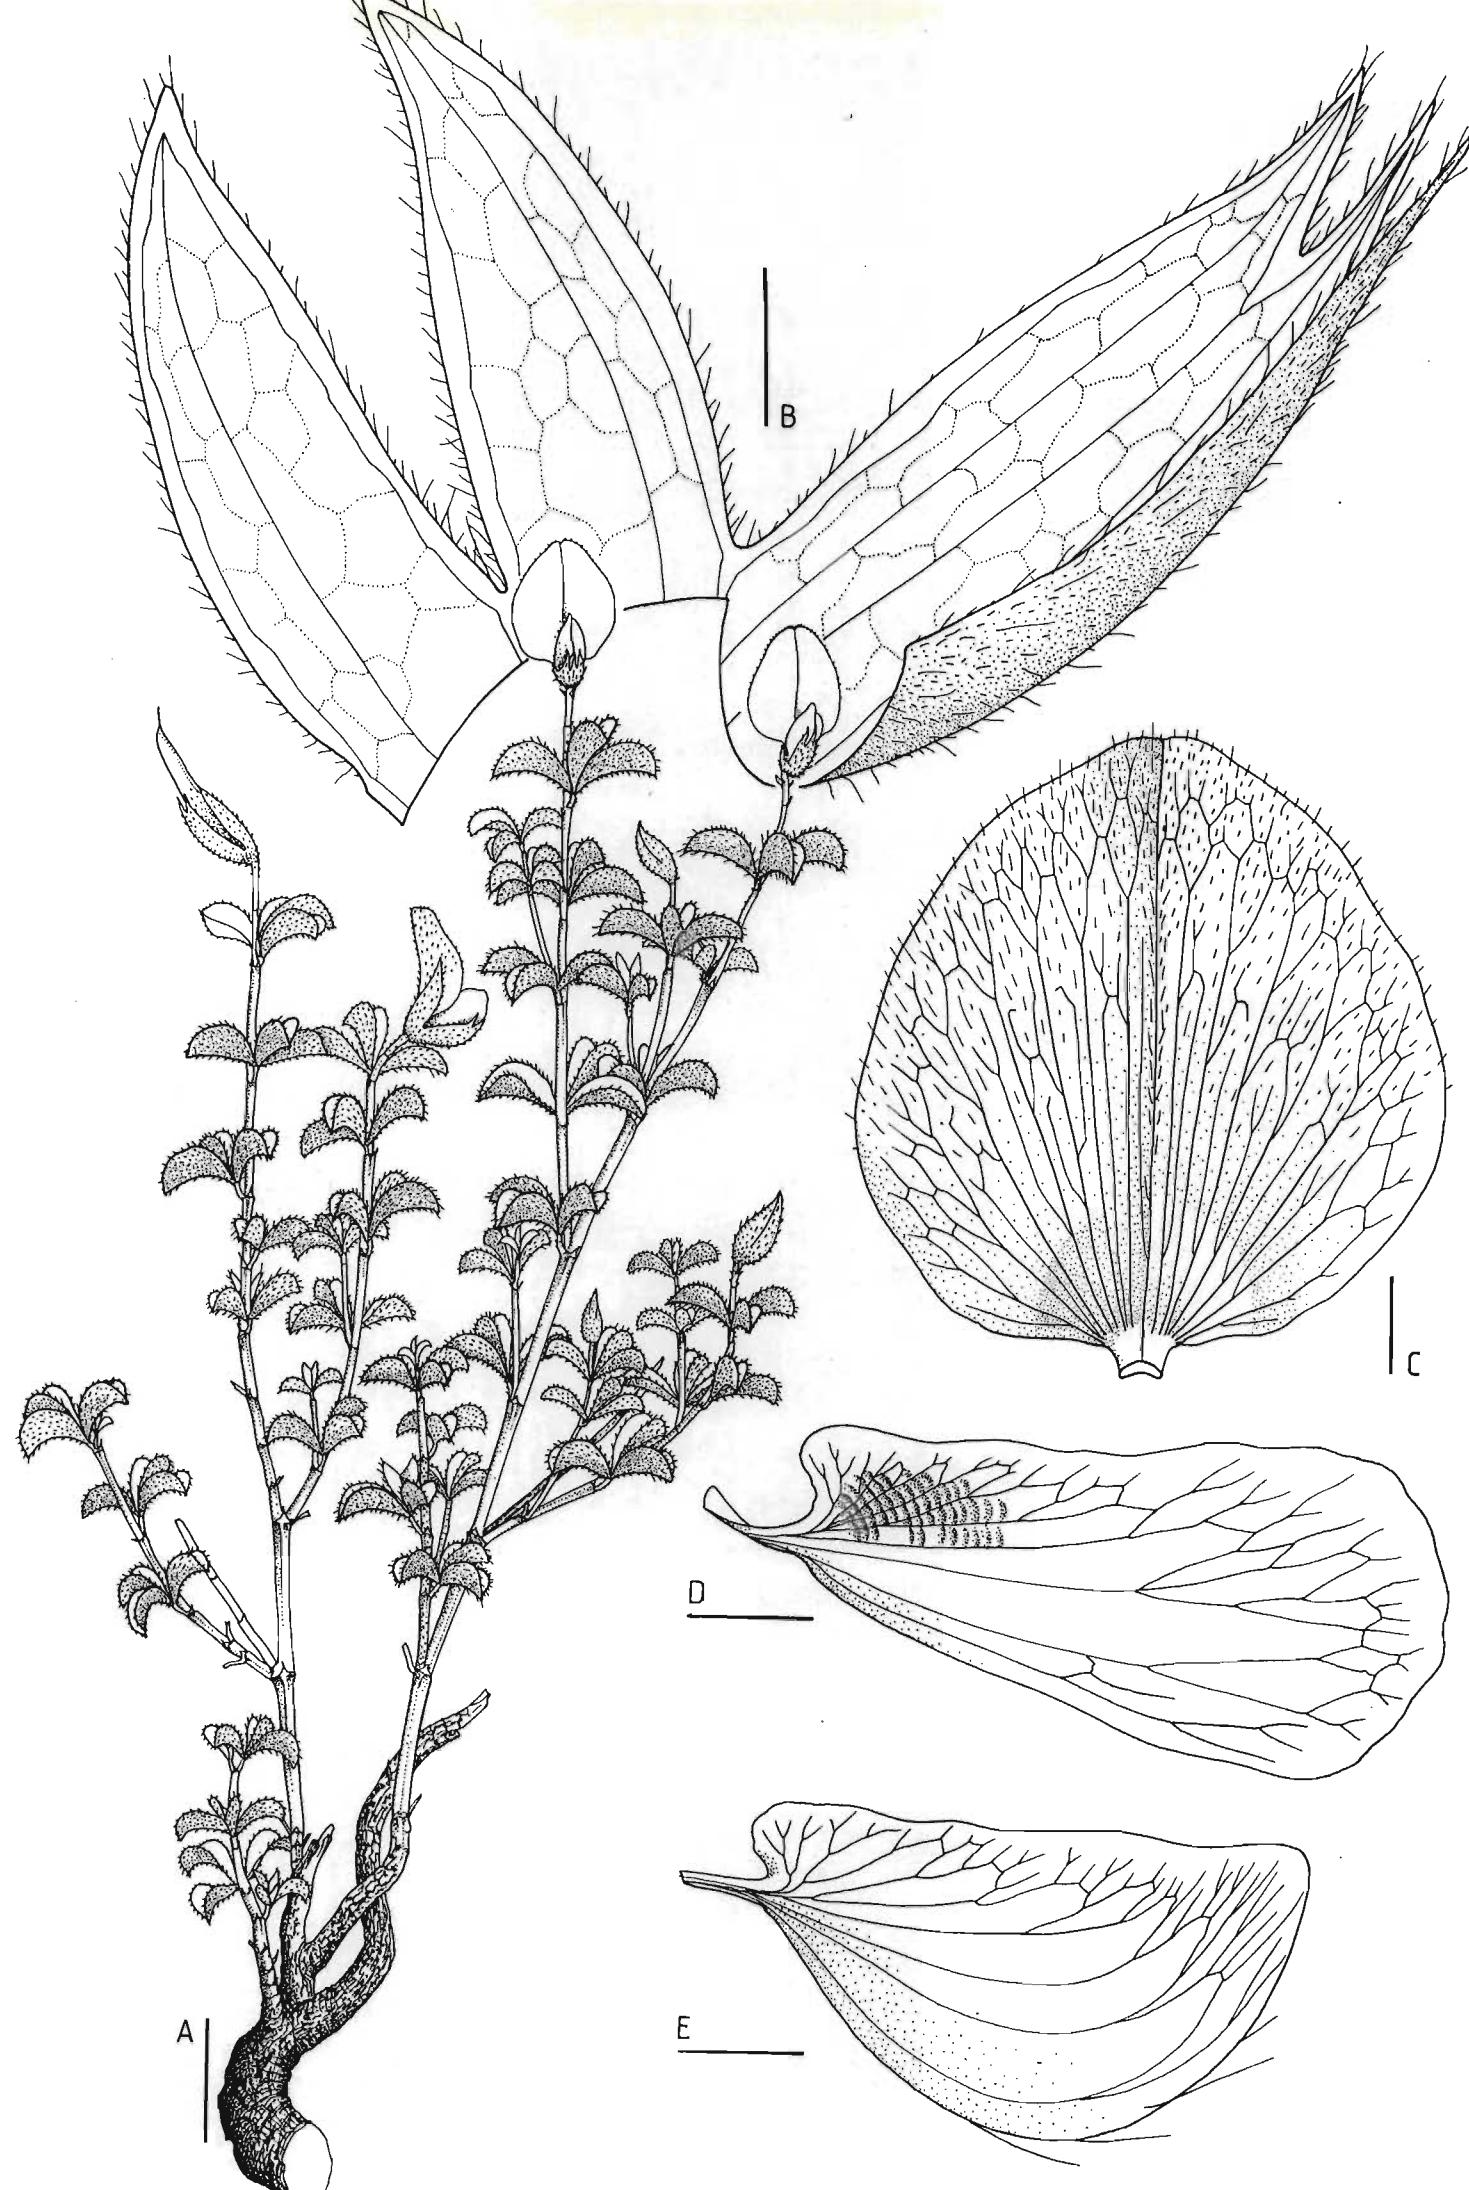

Figure 91. Recorded distribution of A. *A. argenteum* and B. *A. pachyphyllum*.

pachyphyllum are white with appressed trichomes and the plants are densely branched shrubs, characters never seen in *A. collinum* which is weakly perennial. A closer ally is *A. argenteum* which is a small shrub of the adjacent interior. It is distinguished by its membranous, weakly conduplicate leaves with pronounced petioles and its smaller flowers with narrower petals.

A. pachyphyllum is a narrow endemic around Bredasdorp in Coastal Renosterbosveld and Coastal Macchia (Figure 91).

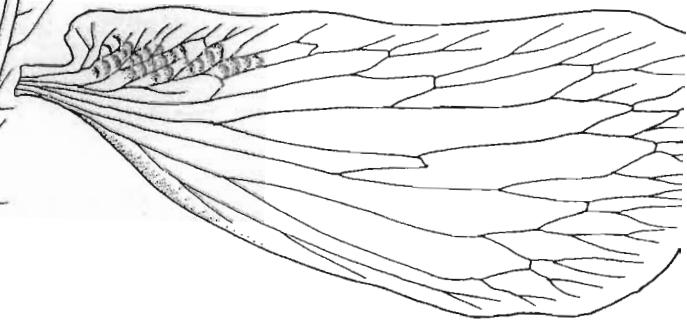

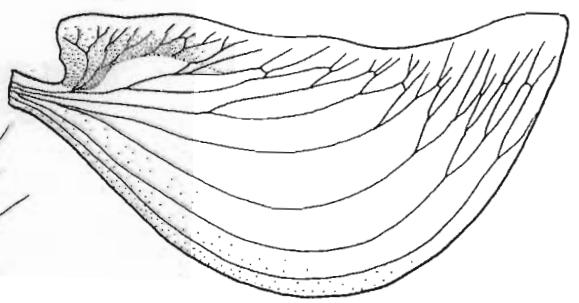

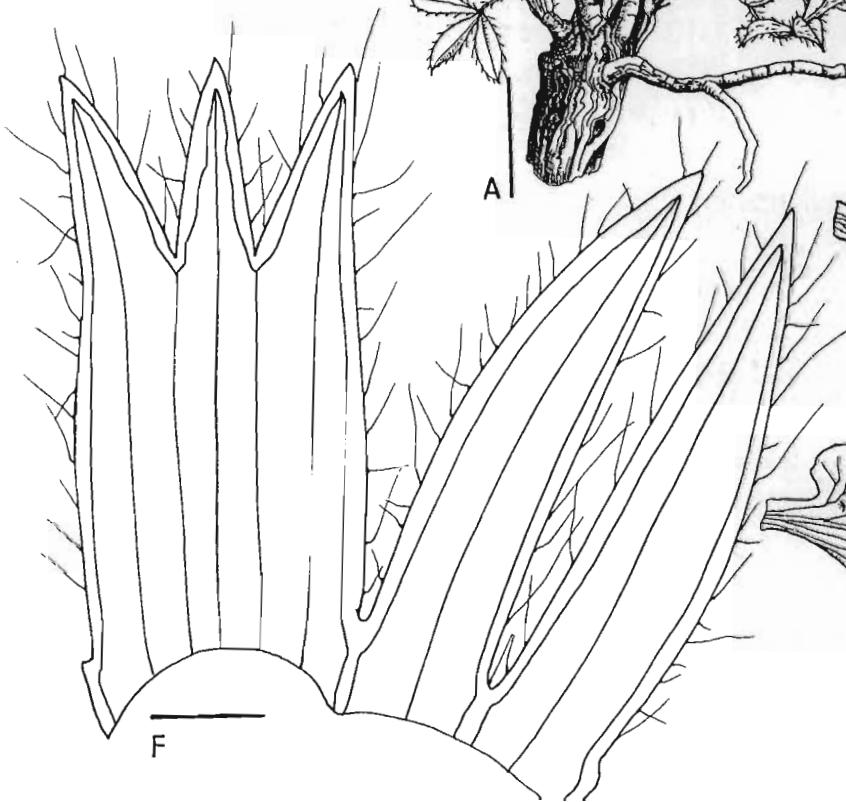

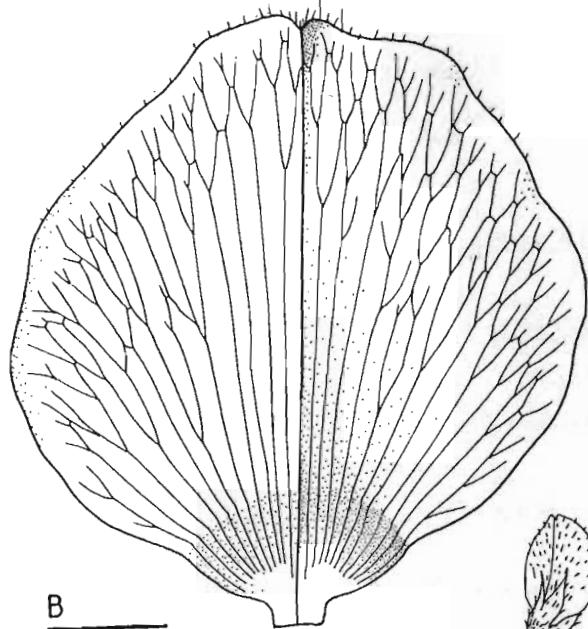

3419 (Caledon): Dasberg, Storms Vlei, (--BB), Stokoe 61545 (SAM); Riversonderend, (--BB), Stokoe 64904 (SAM); Caledon, (--DA), Bolus 6477 (BOL); Park s.n. (NBG); farm "The Bath", (--DA), Guthrie s.n. 44

34. *Argyrolobium barbatum* (Meisn.) Walp., Repert. Bot. Syst. 2: 845 (1843); Harv.: 74 (1862); Benth.: 345-346 (1844). Type: eastern Cape, Uitenhage, banks of the Koega River, Krauss 928 (B†; W!, lecto. selected here).

Figure 90

Argyrolobium pachyphyllum. A. Habit (bar = 20 mm); B. calyx (bar = 2 mm); C. standard (bar = 2 mm); D. wing (bar = 2 mm); E. keel (bar = 2 mm). Voucher: Burgers 1580.

Chasmone barbata Meisn. :77 (1843). Type: as above.

Dwarf shrub up to 0.4 m tall, forming clumps, stems well branched, pilose, becoming glabrous. *Leaves* pilose, conduplicate; leaflets 8--12 x 4--6 mm, ovate to obovate, apex acute to recurvomucronate, apiculate; petiole 5--13 mm long; stipules 4--7 x 2--3 mm, connate in the basal third. *Inflorescence* 1--2(--3)-flowered, terminal, becoming leaf-opposed; peduncle 10--20 mm long; bracts 5--6 x 0.75--1 mm, lanceolate; bracteoles 3--4 x 0.75 mm, linear. *Calyx* pilose, deeply bilabiate; upper lobes 10--12 mm long, upper sinus 2--2.5 mm deep, lower lip 11--14 mm long, lobes acute, 2.5--3.5 mm long. *Corolla* yellow; standard suborbicular, 10--12 x 10--11 mm, adaxial surface sericeous, claw c. 1 mm long; wings oblong, 9--12 x 3--4 mm, glabrous or sparsely sericeous in the distal third, petal sculpturing lunate, in the upper basal zone, claw 1.5--2 mm long; keel cymbiform, 9--12 x 3--4 mm, claw 1--1.5 mm long. *Stamens* monadelphous, sheath completely fused above. *Ovary* narrowly oblong, 5--8 mm long; style 4--6 mm long. *Fruit* sparsely pilose, moderately compressed, 15--30 x 4.5--5 mm. *Seed* suborbicular, 3--4 mm in diameter, dark brown.

45

A. barbatum is a rare endemic in Addo Bush, a southern form of Valley Bushveld (Figure 94). Plants are distinctive with a rufous, pilose indumentum and partially

Figure 92

Argyrolobium barbatum. A. Habit (bar = 20 mm); B. standard (bar = 2 mm); C. leaf with fused stipules (bar = 2 mm); D. keel (bar = 2 mm); E. wing (bar = 2 mm); F. calyx (bar = 2 mm). Voucher: Janus & Sidey 733.

connate stipules. The flowers are borne singly or in pairs. In these characters the species resembles *A. campicola* which is however allopatric and distinguished by its short petioles, herbaceous habit and sparsely pilose wing petals with lamellate sculpturing.

3325 (Port Elizabeth): Sandflats, (--BD), *Sidey* 733 (MO); *Acocks* 13628 (PRE); *Story* 2356 (GRA); Ngnaga, between Port Elizabeth & Grahamstown, (--BD), *Bond* 1236 (NBG); Koegakopje, Zwartkopsjan, (--CD), *Zeyher* 2305 (G, P, S, SAM, TCD); 22 km from Port Elizabeth on the rd. to Grahamstown, (--DB), *Germishuizen* 1402 (PRE).

35. *Argyrolobium collinum* Eckl. & Zeyh. in Enum. Pl. Afr. Austr. 2: 186 (1836); Walp.: 507 (1839); Walp.: 631 (1843); Harv.: 72 (1862); Harms: 178 (1917). Type: eastern Cape, Uitenhage, Addo and near Bosjesmansrivier, *Ecklon* & *Zeyher* 705 (K!, lecto. selected here; BM!, E!, TCD!, isolecto.).

Argyrolobium podalyrioides Dümmer: 273 (1912), *synon. nov.* Type: Grahamstown, on grassy hills, *Mac Owan* 481 (K!, lecto. selected here; BOL!, GRA!, K!, NY!, PRE!, TCD!, isolecto.); Grahamstown, Bothasberg, *Tyson s.n.* (K!, syn.).

Herb 0.15--0.5 m tall, erect becoming decumbent; stems poorly branched, weakly perennial, velutinous, becoming glabrous. *Leaves* sericeous to velutinous; leaflets

narrowly to broadly obovate, 6--20 x 3--11 mm, often conduplicate, apex rounded to emarginate, apiculate; petiole 1-2.5(--4) mm long; stipules 2-4 x 0.75--1 mm, often recurved, setaceous or lanceolate. *Inflorescence* 1(--2)-flowered, leaf-opposed; peduncle 0--2 mm long; bracts narrowly linear, 0.7--1.5 mm long, bracteoles narrowly linear, 0.5--1 mm long. *Flowers* dimorphic. *Calyx* velutinous, deeply bilabiate; upper lobes 8--10 mm long, upper sinus 5.5--8 mm deep, lower lip 9--11 mm long, lobes acute, 2--4 mm long. *Corolla* yellow; standard broadly obovate to suborbicular, 10--13 x 10--11 mm, adaxial surface sericeous, base rounded, claw 1--1.5 mm long; wings oblong to obovate, 9--13 x 3--5 mm, often sparingly sericeous, with lunate-lamellate sculpturing in the basal and upper central zones, claw 1--2 mm long; keel acutely cymbiform, 8--12 x 4--5 mm, claw 1.5--2 mm long. *Stamens* monadelphous, sheath completely fused above. *Ovary* narrowly oblong, 6--7 mm long; style 4--6 mm long. *Fruit* velutinous, 25--40 x 4--5 mm. *Seed* suborbicular, 1--1.5 mm in diameter, pale yellow.

Argyrolobium collinum is herbaceous and seldom exceeds 0.4 m, plants soon become moribund in unburnt grassland. Solitary (occasionally paired), sessile, chasmogamous flowers characterise this species. Unfortunately many of the vegetatively similar species produce solitary, sessile cleistogamous flowers and this may cause some confusion in fruiting specimens. However, fruits set through cleistogamy are easily distinguished by their poorly developed calyces.

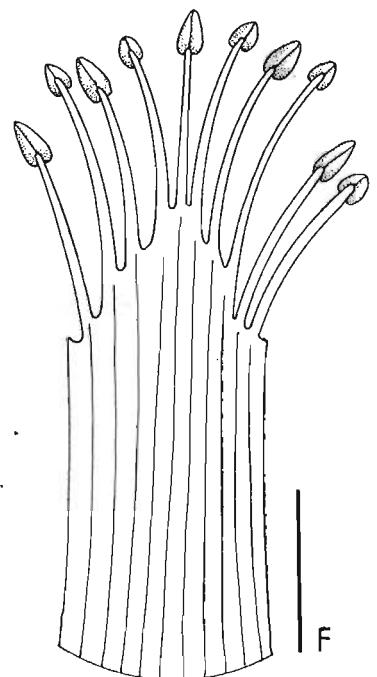

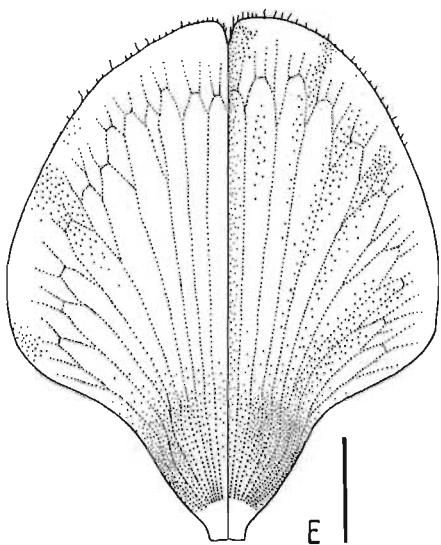

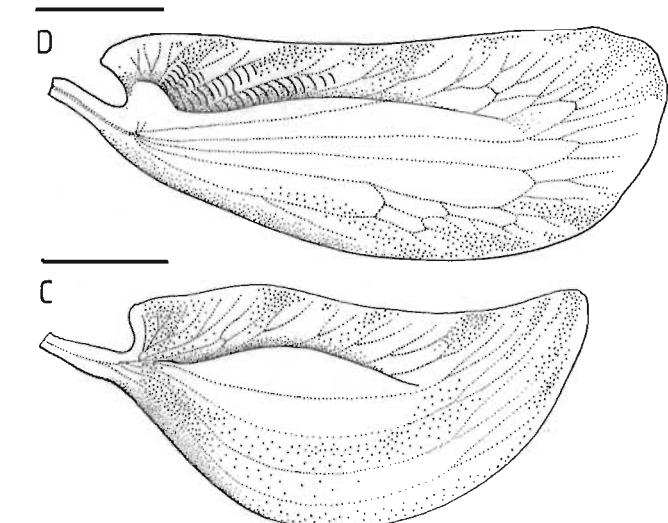

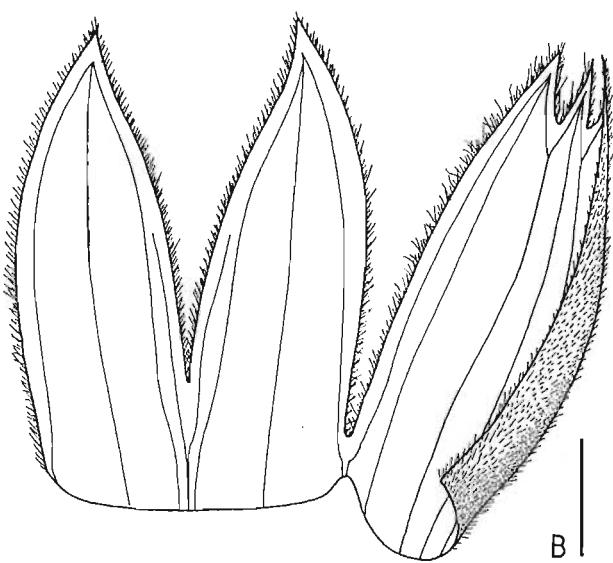

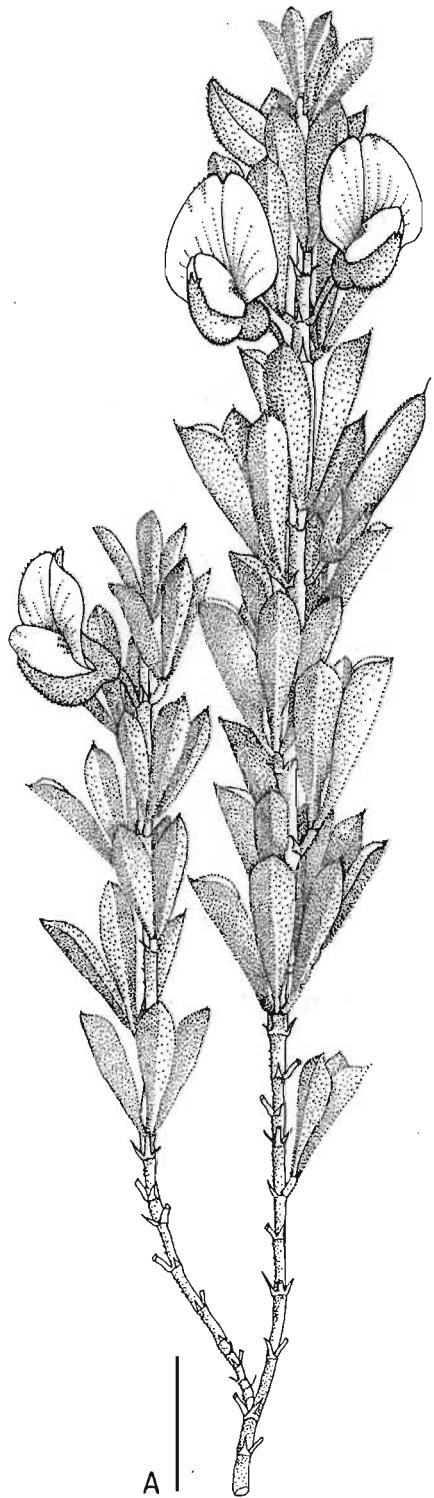

in accordance with the state of surrounding vegetation. Robust coppice growth, with broadly obovate leaflets, characterises resprouting specimens and spindly decumbent plants with narrowly obovate leaflets occur in moribund vegetation.

The reduction of *Chasmone apiculata* E. Mey. to synonymy with *A. collinum* (Benth. 1844, Harv. 1862, Walp. 1839 & 1843) is not supported. The type of *C. apiculata* was misidentified because the fruits are solitary, subsessile and leaf-opposed. These fruits were produced through cleistogamy as is evident by their diminutive calyces and therefore constitute *A. molle* (hence the clear leaflet venation).

A. harmsianum is allied to *A. collinum* producing similar chasmogamous inflorescences. It is distinguished by its oblong leaflets with glabrescent adaxial surfaces.

A. collinum commonly occurs in grasslands associated with False Macchia (Figure 94).

3322 (Oudtshoorn): Lange Kloof, George, (--CB), Krauss 919 (NY). 3323 (Willowmore): Joubertina, (--DD), Esterhuysen 21215 (BOL, PRE); Esterhuysen 24224 (BOL); Esterhuysen 19946 (BOL); Edwards & Ackermann 476 (NU). 3325 (Port Elizabeth): Atalaya Valley, Zuurberg, (--AD), Johnson 763 (BOL);

Grahamstown, (--BC), *Tyson* 15373 (SAM); Van Staden's Flower Reserve, (--CC), *Drège s.n.* (S); *Dahlstrand* 1951 (GRA, MO); *Dahlstrand* 2567 (GRA, MO, PRE); *Salter* 377 (BM); flats between Zwartkop & Van Staden's Rivers, (--CC), *Zeyher* 705 (BM, E, K, TCD); Uitenhage, Koegakopjie, Zwartkopsjan, (--CD), *Zeyher* 2301 (P); Addo, (--DA), *Drège s.n.* (S). 3326 (Grahamstown): Assagaibos, (--AD), *Zeyher* 2302 (BM, PRE); Faraway, near Grahamstown, (-BC), *Jacot Guillarmod* 8934 (GRA); *Edwards & Ackermann* 481 & 487 (NU); Grahamstown, (--BC), *Bolton s.n.* (TCD); *Schlechter* 2623 (GRA); *Breyer* 16859 (PRE); Gunfire Hill, (--BC), *Rennie* 479 (BOL); *MacOwan* 481 (BOL, GRA, NH, NY, TCD); Bothasberg, (--BC), *MacOwan* 799 (NY); hill above hospital, (--BC), *Daly & Cherry* 921 (GRA); Trapp's Valley, (--BD), *Compton* 19111 (NBG); Alexandria, Kolsrand, (--CB), *Archibald* 4084 (GRA); *Galpin* 10679 (BOL, PRE); Bathurst, (--DB), *Sidey* 3142 (PRE).⁴⁶

36. *Argyrolobium harmsianum* Schlechter ex Harms in Ber. Deutsch. Bot. Ges. 35: 183 (1917). Type: Southwestern Cape, on hills at Cape Agulhas, *Schlechter* 10565 (G!, lecto. selected here; E!, MO!, PRE!, S!, W!, isolecto.).

Herb, up to 0.2 m tall, erect, sparsely branched, stoloniferous, stems annual, sericeous. Leaves sparsely sericeous abaxially or glabrescent; leaflets obovate to

Figure 93

Argyrolobium collinum. A. Flowering branch (bar = 20 mm); B. calyx (bar = 2 mm); C. keel (bar = 2 mm); D. wing (bar = 2 mm); E. standard, abaxial surface (bar = 2 mm); F. androecium (bar = 2 mm). Voucher: *Edwards & Ackermann* 481.

oblong rarely oblanceolate, 10--25 x 3--9 mm, apex rounded, usually apiculate; petiole 0--1 mm long; stipules subulate to linear, 1--3 x 0.5 mm. *Inflorescence* solitary-flowered, leaf-opposed; bracts linear 2.5--3 x 1 mm; bracteoles lanceolate, up to 3 x 1 mm. *Calyx* shortly pilose, upper lip 8--11 mm long, sinus 6--9 mm deep; lower lip 10--12 mm long, lobes 3.5--5 mm long, medial lobe linear. *Corolla* yellow; standard suborbicular, 11--14 x 10--12 mm, adaxial surface sparsely sericeous, base obtuse, claw 1--2 mm long; wings oblong to obovate, 10--12 x 4--5 mm, with lunate-lamellate sculpturing in the upper basal zone, sparsely sericeous distally, claw 1--2 mm; keel cymbiform, 10--12 x 4--5 mm, claw 2 mm. *Stamens* monodelphous. Ovary narrowly oblong, 6--9 mm long densely sericeous or laterally glabrous; style 4--5 mm long. *Fruit* densely sericeous, compressed, 25--35 x 4 mm, erect. *Seed* not seen.

The habit and solitary flowers of *A. harmsianum* are very similar to high altitude forms of *A. harveyanum* however these similarities appear to be convergent. The androecia of *A. harveyanum* are always pseudodiadelphous with the vexillary stamen largely free and this has not been observed in *A. harmsianum*. *A. collinum* is its closest ally sharing a similar habit and inflorescence structure. It is distinguished by its densely sericeous, conduplicate leaves which are usually imbricate and its glabrous wing petals.

Argyrolobium harmsianum is endemic to the limestones around Bredasdorp in

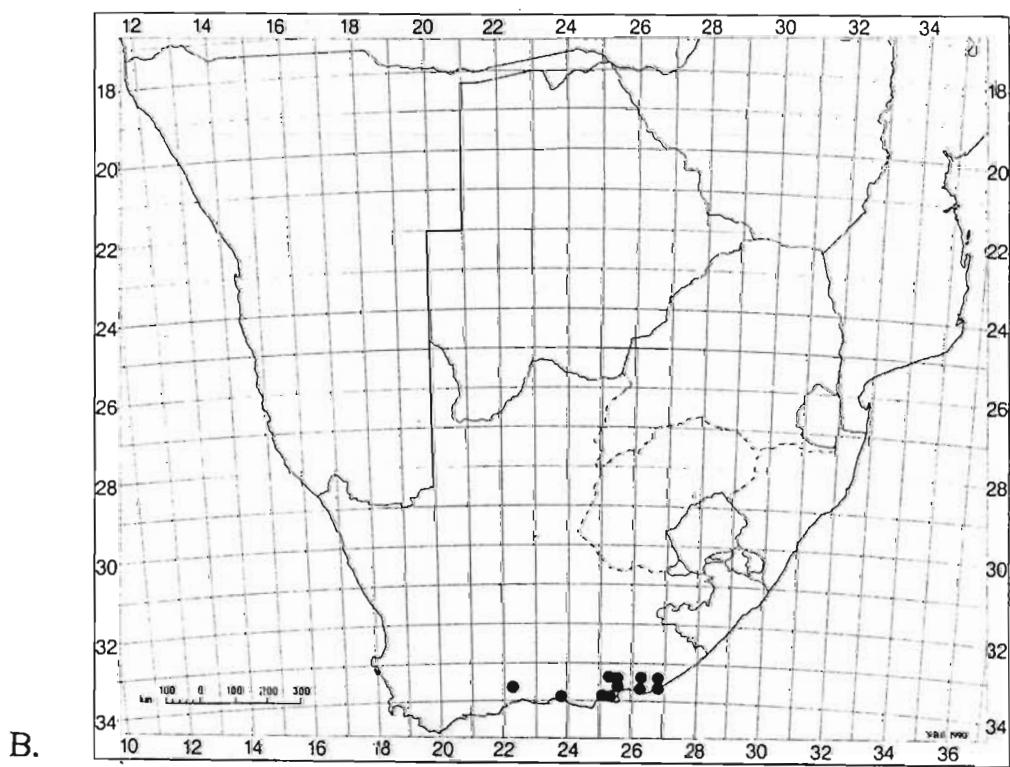

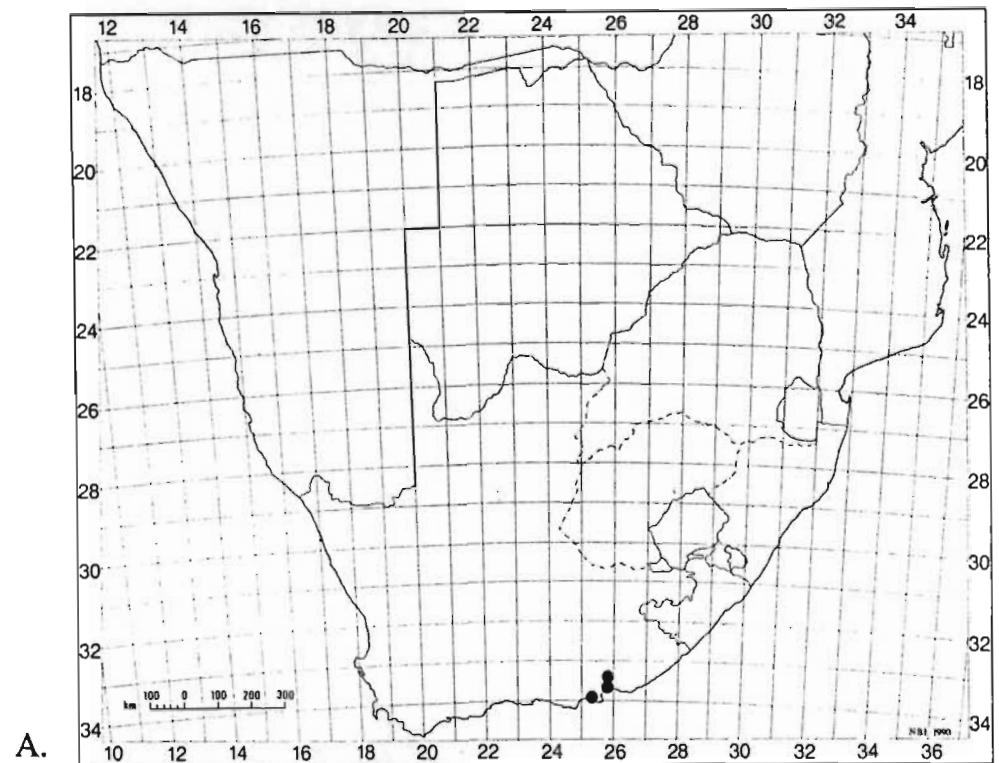

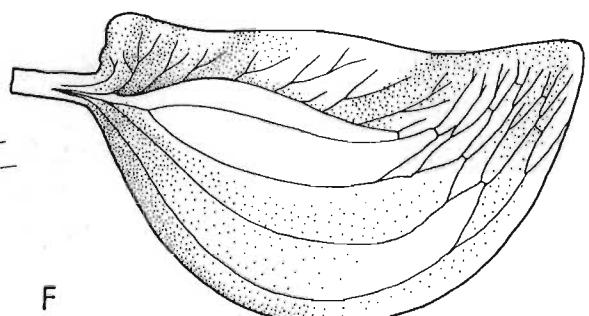

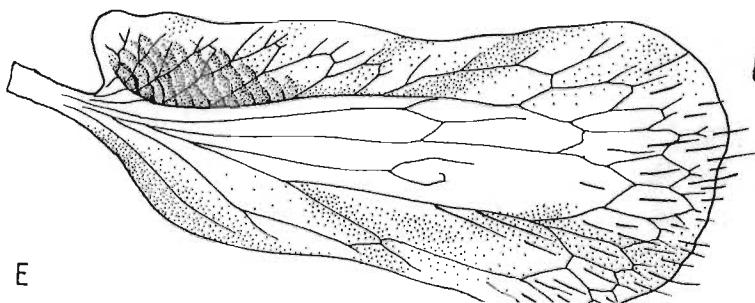

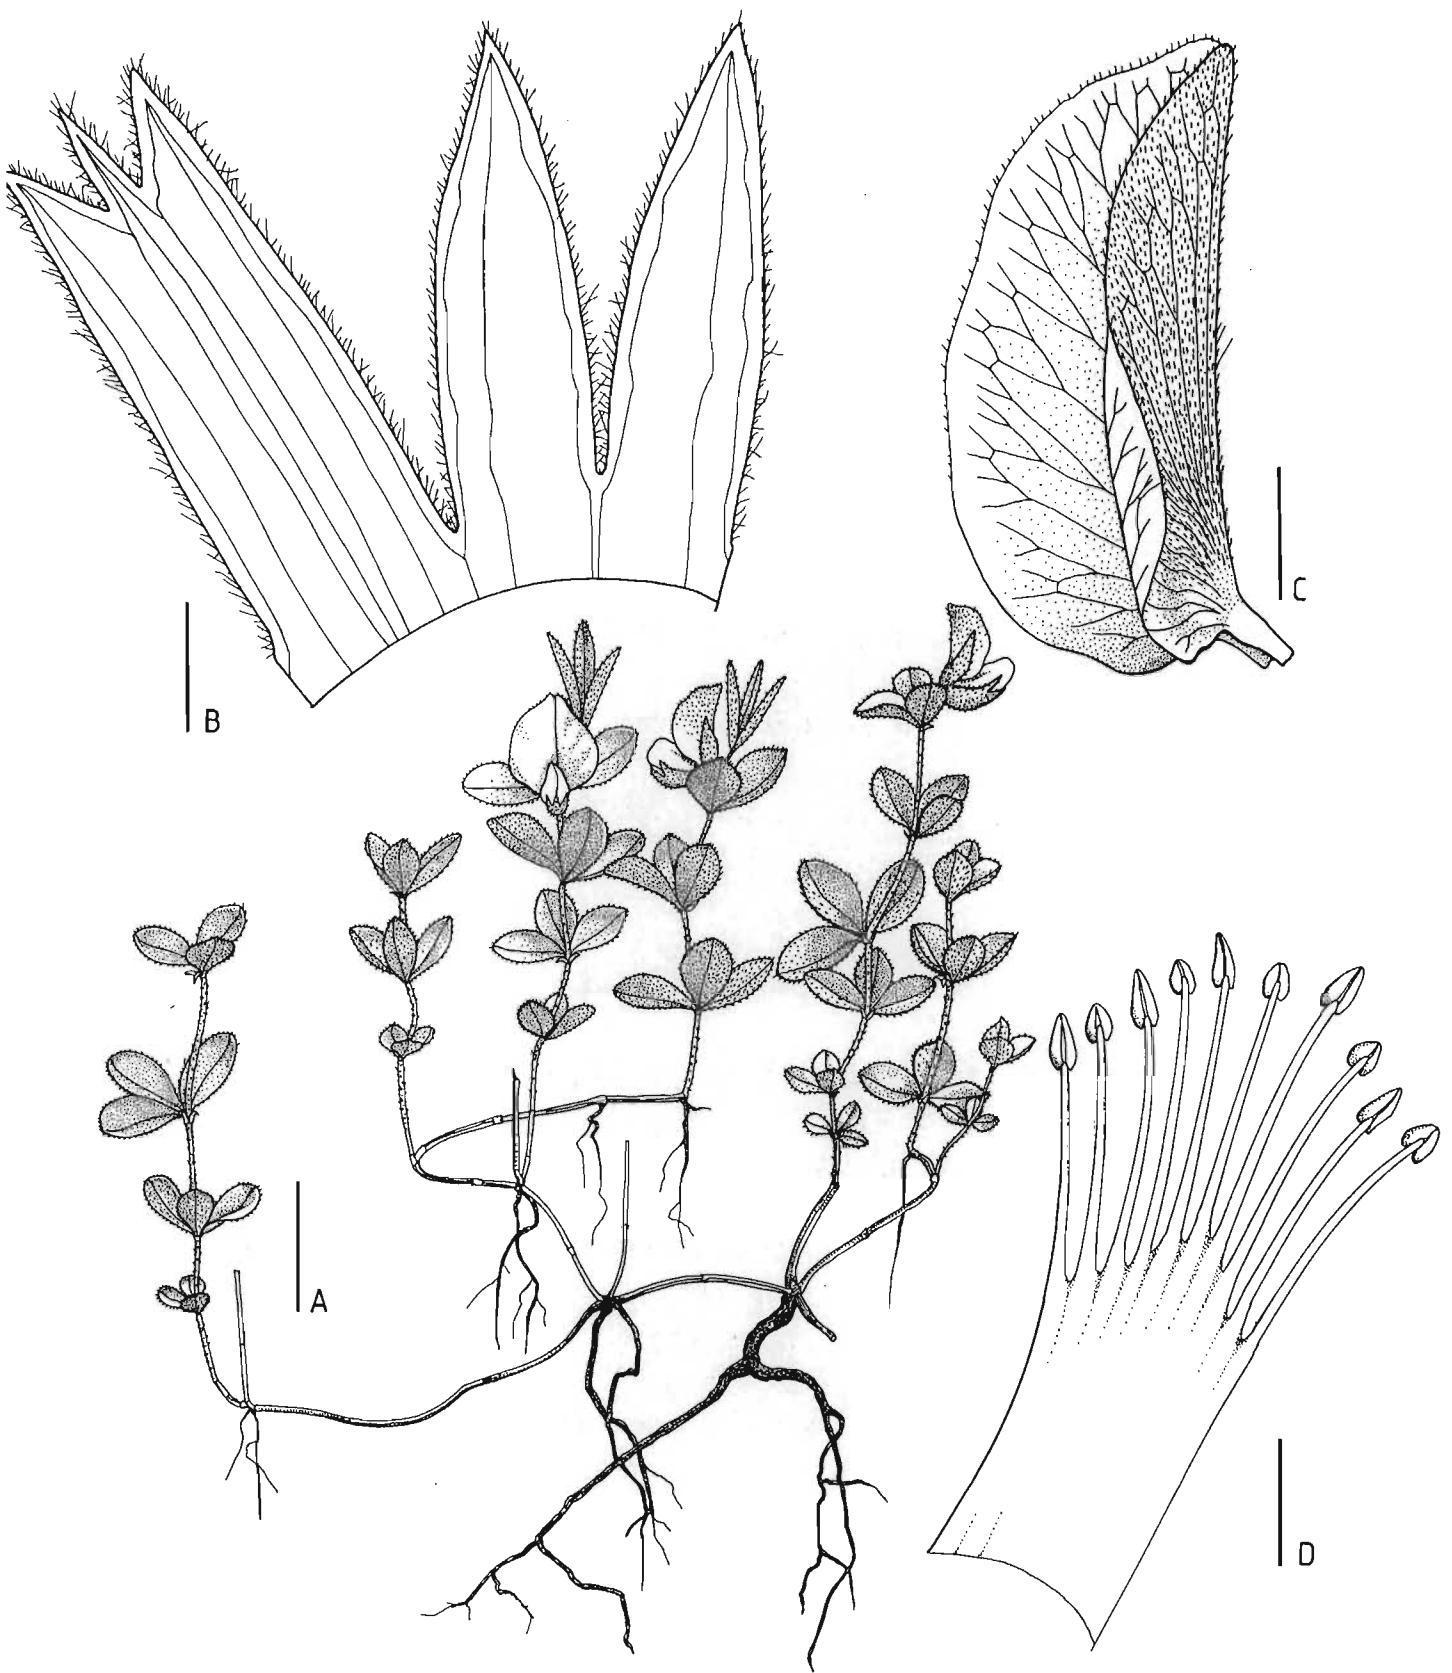

Figure 94. Recorded distribution of A. *A. barbatum* & B. *A. collinum*.

E

F

Coastal Macchia (Figure 81).

3420 (Bredasdorp): De Hoop, Hamerkop Farm, (--BC), *Van Wyk 1599* (STE); De Hoop (--BC), *Levyns 10703* (BOL); near Cape Agulhas, (--CA), *Hugo 1752* (PRE); *Pillans 8175* (BOL); *Schlechter 10565* (E, G, MO, PRE, S, W).⁴⁷

37. *Argyrolobium filiforme* (Thunb.) Eckl. & Zeyh., Enum. Pl. Afr. Austr. 2: 186 (1836); Walp.: 508 (1839); Walp.: 632 (1843); Benth.: 344--345 (1844); Harv.: 73 (1862); Harms: 178 (1917). Type: Cape, Crests of the Hottentots Holland Mountains, *Thunberg s.n. sub THUNB 17374* (UPS!, lecto. selected here).

Galega filiformis Thunb.: 133 (1800); Thunb.: 600 (1823). Type: as above.

Argyrolobium stenorhizon Oliv.: t. 1525 (1886) *synon. nov.* Type: Cape Province, near Rondebosch, *H. Bolus 7013* (K!, lecto. selected here; BOL!, G!, NH!, PRE, isolecto.); without precise locality, *Zeyher 387* (BM!, K!, syn.).

Argyrolobium muirii L. Bol.: 127 (1915), *synon. nov.* Type: Cape Province, Bovenplaats, near Albertinia, *Muir 1374* (BOL!, lecto. selected here; PRE!, isolecto.).

Herb, 0.1--0.3 m tall, erect, sparsely branched, stems weakly perennial, sericeous to velutinous, plants solitary, tufted or forming small clumps via subterranean

Figure 95

Argyrolobium harmsianum. A. Habit (bar = 20 mm); B. calyx (bar = 2 mm); C. standard, lateral view (bar = 2 mm); D. androecium (bar = 2 mm); E. wing (bar = 2 mm); F. keel (bar = 2 mm). Voucher: *Levyns 10703*.

stolons. *Leaves* sometimes dimorphic; lower leaflets broadly obovate, elliptic, to narrowly lanceolate, 7–30 x 3–5 mm, shortly pilose to glabrescent, petiole 3–18 mm long; upper leaflets conduplicate, linear to oblanceolate, 20–40 x 2–4 mm, abaxially sericeous, apex acute, apiculate, petiole 2–15 mm long; stipules deltoid to subulate, 1–3 x 0.5 mm. *Inflorescence* 1–3(–5)-flowered, sessile, leaf-opposed; bracts linear 1–3 x 0.5 mm; bracteoles setaceous, up to 2 mm long. *Calyx* sericeous, upper lip 6–8 mm long, sinus 3–5 mm deep; lower lip 6–9 mm long, lobes 1–3 mm long, medial lobe linear. *Corolla* yellow; standard suborbicular, 8–11 x 8–12 mm, adaxial surface sparsely sericeous, base cordate, claw 1–1.5 mm long; wings oblong to obovate, 7–10 x 3–4 mm, sometimes distally sericeous, with lunate-lamellate sculpturing in the upper basal and sometimes in the lower basal zones, claw 1–1.5 mm long; keel cymbiform, 7–9 x 3.5–5 mm, claw 1–1.5 mm. *Stamens* monodelphous. Ovary narrowly oblong, 4–6 mm long, densely sericeous or laterally glabrous; style 3–4 mm long. *Fruit* sericeous, compressed, linear or arcuate, 18–45 x 3.5–4 mm, erect. *Seed* orbicular or irregular, 1.5–2 mm.

Argyrolobium filiforme and its close ally *A. aciculare* occur in the southern Cape and are replaced by *A. harveyanum* to the north. The species can be distinguished on inflorescence structure; *A. harveyanum* always has sessile, solitary flowers and *A. filiforme* has sessile, multi-flowered fascicles which appear pedunculate due to retarded apical leaf development and in *A. aciculare* the fascicles are often

pedunculate. *A. aciculare* is also distinguished from *A. filiforme* by its monomorphic, ericoid leaflets usually borne atop reduced petioles (1--3 mm). The leaves of *A. filiforme* are usually slightly dimorphic.

Past researches have included *A. angustissimum* within *A. filiforme*. However the flowers of the former are large and red-yellow which indicates a strong alliance with *A. tuberosum*. There are no intermediates which link it to *A. filiforme* in terms of floral morphology (Figure 96).

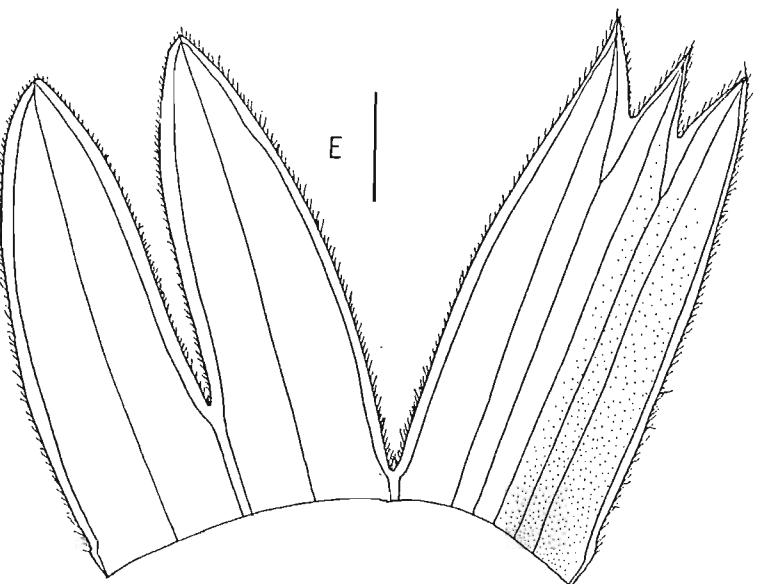

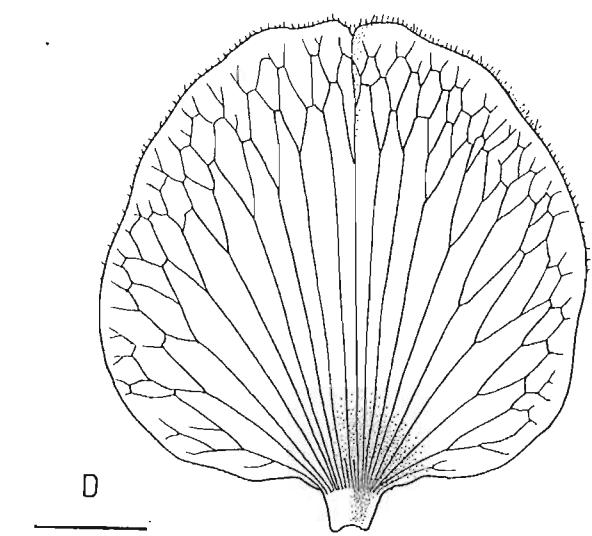

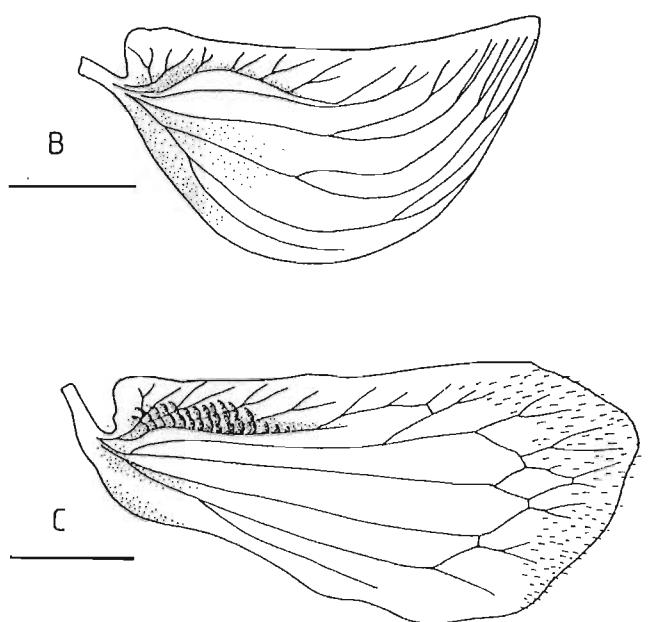

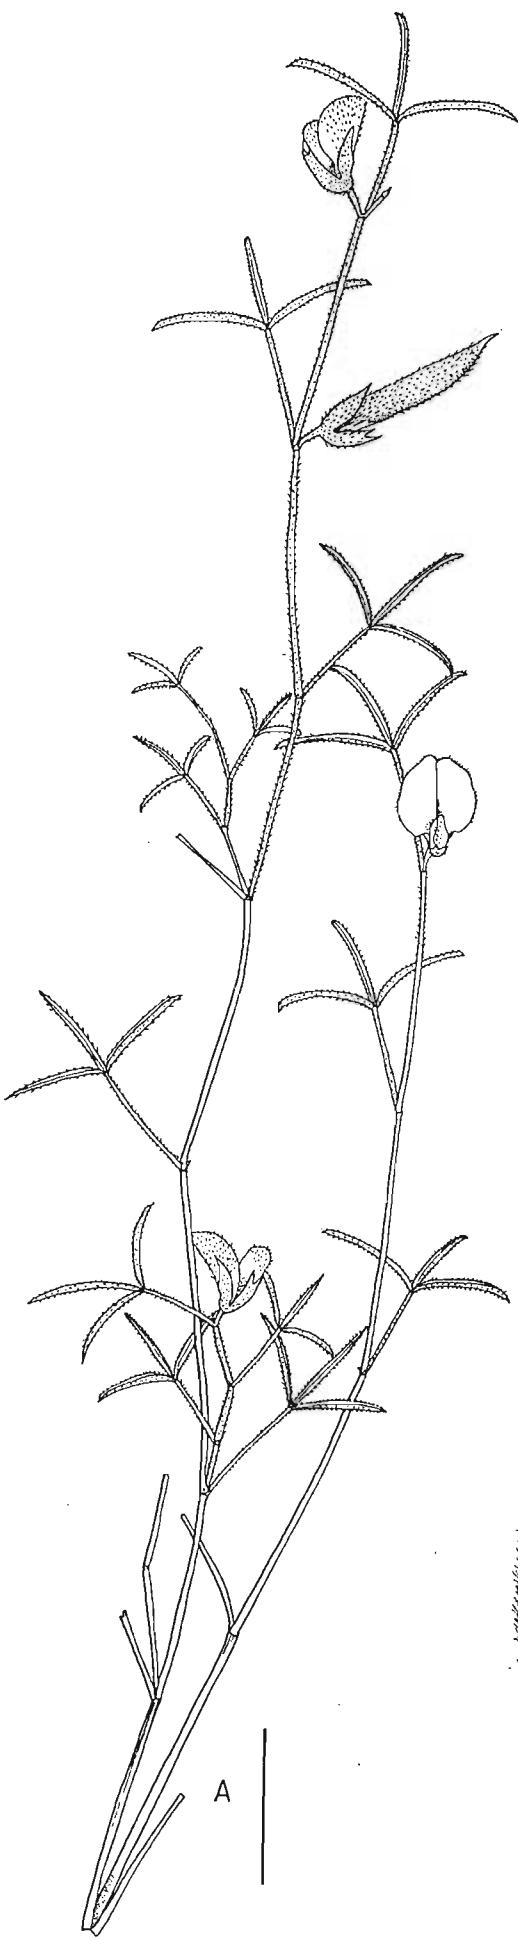

A. filiforme occurs mainly in Coastal Macchia but gatherings have also been made in Macchia and False Macchia vegetation types (Figure 97). Summer flowering predominates but this is probably induced by burning. Cleistogamy is rare in this species.

(UPS). 3419 (Caledon): Franschoek, (--AA), *Phillips* 1093 (SAM); Elgin, Palmiet River, (--AA), *Esterhuysen* 8422 (BOL); Klein Hagelkraal, (--DA), *Hugo* 1713 (STE); Mierkraal, (--DB), *Schlechter* 10508 (E, GRA, PRE). 3421 (Riversdale): Bovenplaats, near Albertinia, (--BA), *Muir* 1374 (BOL, PRE); Botteliersfontein, (--BA), *Muir* 1158 (BOL, PRE).

38. *Argyrolobium rarum* Dümmer in Kew Bull.: 273 (1912). Type: Oudtshoorn, Avontuur, Uniondale, *Fourcade* 2985 (BOL!, neo. selected here). [Original type: Grahamstown, Hellpoort (Hельспорт), *MacOwan* 946].

Herb, up to 0.4 m tall, decumbent or scandent, sparsely branched, stems weakly perennial, shortly sericeous. *Leaves* rarely dimorphic; lower leaflets rarely broadly obovate, 6--8 x 3--4 mm, shortly pilose abaxially, glabrescent adaxially, petiole 6--8 mm long; upper leaflets conduplicate, linear, 8--23 x 2 mm, abaxially shortly sericeous, apex acute, petiole (8--) 15--25 mm long; stipules subulate, 1 x 0.25--0.5 mm. *Inflorescence* sessile, solitary-flowered, leaf-opposed; bracts linear 1--2 x 0.5 mm long; bracteoles setaceous, up to 1 mm long. *Calyx* shortly sericeous, upper lip 7--9 mm long, sinus 5--6 mm deep; lower lip 8--10 mm long, lobes 2--3 mm long. *Corolla* yellow; standard suborbicular, 9--12 x 9--12 mm, adaxial surface shortly sericeous, base obtuse, claw 1 mm; wings oblong-obovate, 9--10 x 4 mm, with lunate-lamellate sculpturing in the upper basal and upper

central zones, claw 1.5--2 mm; keel deeply cymbiform, 8--9 x 4--5 mm, claw 2 mm. *Ovary* narrowly oblong, 4--5 mm long densely sericeous or laterally glabrous; style 4--5 mm long. *Fruit* sericeous, compressed, linear or arcuate, 30--35 x 3.5--4 mm. *Seed* trapezoid or irregular, 1.5 mm, slightly compressed.

This species is closely allied to *A. harveyanum* but is distinguished by the long petioles of the upper leaves. In *A. harveyanum* these leaves are always subsessile. The long petioles and linear leaflets are similar to terete forms of *A. lunare* however the sessile, solitary flowers, and the occurrence of cleistogamy in *A. rarum* clearly distinguish it. The species occurs in False Macchia and the disjunctions of this vegetation type are reflected in its distribution (Figure 100).⁴⁸

39. **Argyrolobium aciculare** Düümmer in Kew Bull.: 271 (1912). Type: southern Cape, Caledon, on the slopes of Houw Hoek, *Bolus* 6934 (BOL, lecto.! selected here; K!, PRE!, isolecto.).

Herb, 0.1--0.25 m tall, erect, sparsely branched, stems weakly perennial, shortly sericeous, plants usually forming small clumps. *Leaves* ericoid, 10--40 x 1 mm, initially shortly sericeous but soon glabrous, except for the pulvini, apex acute, petiole 2--4 mm long, stipules deltoid, 2--4 x 0.75--1 mm. *Inflorescence* 1--3(--5)-flowered, usually pedunculate, leaf-opposed; bracts linear 3--5 x 0.5 mm; bracteoles lanceolate to deltate, up to 2.5--4 x 0.5--0.75 mm. *Calyx* shortly sericeous, upper lip 6--8 mm long, sinus 5--6 mm deep; lower lip 7--9 mm long, lobes 1--3 mm long. *Corolla* yellow; standard suborbicular, 8--11 x 10--12 mm, adaxial surface sparsely sericeous, base cordate, claw 1--1.5 mm long; wings oblong to obovate, 8--10 x 3--4 mm, sometimes distally sericeous, with lunate-lamellate sculpturing in the upper basal and sometimes in the lower basal zones, claw 1--1.5 mm long; keel cymbiform, 8--10 x 3.5--4 mm, claw 1--1.5 mm. *Stamens* monodelphous. *Ovary* narrowly oblong, 4--6 mm long, densely sericeous or laterally glabrous; style 3--4 mm long. *Fruit* shortly sericeous, compressed, linear, 20--40 x 3.5--4 mm. *Seed* orbicular or irregular, 1.5--2 mm.

A. aciculare is strongly allied to *A. filiforme* but is distinguished by its monomorphic, glabrous, ericoid leaves and its pedunculate inflorescences with

prominent bracts and bracteoles.⁴⁹

A. aciculare is limited to Macchia around Caledon (Figure 97). Cleistogamy has not been recorded in this species.

3418 (Simonstown): Kogelberg Forest Reserve, (--BD), *Boucher* 1782 (STE); *Van Wilgen* 106 (STE). 3419 (Caledon): Houw Hoek, *Bolus* 6934 (BOL, K, PRE); Palmiet River Mouth, (--AA), *Stoke* 56255 & 55964 (SAM); *Stoke* 8797 (BOL); *Esterhuysen* 12559 (BOL, NBG); *Esterhuysen* 13704 (BOL); Onrust River Mountains, (--AC), *Esterhuysen* 4241 (BOL); Kleinmond, (--AC), *De Vos* 463 & 1152 (STE).

(TCD!, syn.); Albany, Williamson & Barber s.n. (TCD!, lecto. selected here; K!, isolecto.).

Argyrolobium uniflorum Harv.: 72 (1862); non Jaub. & Spach (1843) *nom. illegit.* Types: as above.

Argyrolobium nigrescens Dümmer in Kew Bull. 272--273 (1912). Types: Natal, Harrismith, Sankey 56 (syn., not traced); Basutoland, Cooper 2179 (K!, syn.); Van Reenen's Pass, 1500--1800 m, Wood 4517 (K!, lecto. selected here; NH!, isolecto.).

Argyrolobium nanum Walp. ex Harms non Burtt Davy: 393--394 (1917), *synon. nov.* Types: Natal, Van Reenen's Pass 1700--2000 m, Wood 5875 (BOL!, lecto. selected here; E!, PRE! isolecto.) & 6602 (E!, syn.).

Herb, up to 40 mm tall, erect, sparsely branched, stems weakly perennial, sericeous to pilose, plants solitary or forming small clumps via subterranean stolons. *Leaves* strongly to weakly dimorphic; lower leaflets broadly obovate, elliptic, to lanceolate 5--15 x 3--10 mm, shortly pilose to glabrescent, petiole 3--8 mm long; upper leaflets conduplicate, linear to oblanceolate, 7--50 x 2--3 mm, abaxially sericeous, apex acute, apiculate, petiole 0--2 mm long; stipules deltoid to lanceolate, 2--5 x 0.5--1 mm. *Inflorescence* solitary-flowered, leaf-opposed; bracts linear 1--3 x 0.5 mm long; bracteoles setaceous, up to 3 mm long. *Calyx* sericeous, upper lip 8--11 mm long, sinus 7--9 mm deep; lower lip 8--10 mm long, lobes 2.5--4 mm long, medial lobe linear. *Corolla* yellow; standard

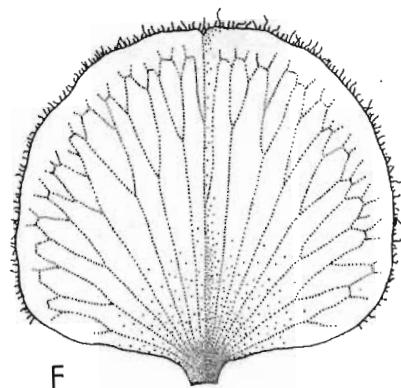

suborbicular, 8.5–13 x 10–16 mm, adaxial surface sparsely sericeous, base cordate, claw 1–2 mm; wings oblong to obovate, 8–13 x 3–4 mm, with lunate-lamellate sculpturing in the upper basal, upper central and lower basal zones, claw 1–2 mm; keel cymbiform, 7–8 x 3–4 mm, claw 2 mm. *Stamens* pseudodiadelphous, with the vexillary filament connected basally. *Ovary* narrowly oblong, 5–6 mm long densely sericeous or laterally glabrous; style 2.5–3 mm long. *Fruit* sericeous, compressed, linear or arcuate, 30–50 x 3–3.5 mm, erect. *Seed* round, trapezoid or irregular, 1.5–2 mm, slightly compressed.⁵⁰

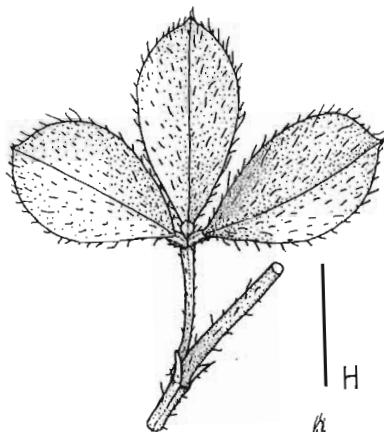

A. nigrescens has been reduced to synonymy with *A. harveyanum* because no discontinuity exists between them. Plants formerly recognised as *A. nigrescens* tend to be short, stoloniferous and have robust tap roots. They occur at high altitudes and have weakly dimorphic, lanceolate leaflets which are glabrescent (Figure 98). Plants which fall into the typical concept of *A. harveyanum* are solitary with fairly small tuberous roots, strongly dimorphic leaves and occur at lower altitudes. These morphological differences appear to have been induced by the altitudinal range of the species. The tendency of var. *nigrescens* to dry black is inconsistent and is thus not diagnostic.

I

A. harveyanum is widespread from coastal grasslands of the eastern Cape, Transkei and Natal into moist grasslands of the Central Natal, Orange Free State, the eastern Transvaal and the highland border between Mozambique and Zimbabwe (Figure 100). The species is common in Dohne and Highland Sourveld, Ngongoni Sourveld and *Themeda-Festuca* Alpine Veld. In the south this species is replaced by *A. filiforme* which differs in its multi-flowered inflorescence and densely sericeous wing petals.⁵¹

41. *Argyrolobium pseudotuberorum* T.J. Edwards in S. Afr. J. Bot. 60(1): 40 (1994). Type: Transvaal, Lydenburg, Buffelskloof Nat. Res., in seepage grasslands above the kloof, near the ranger's homestead, *Edwards & Burrows* 1019 (NU!, holo.).

Herb, 0.12--0.6 m tall, erect; stems triangular, sparingly branched, weakly perennial, sericeous, becoming glabrous; lignotubers turbinate. Leaves sparsely sericeous; leaflets oblanceolate to narrowly obovate, 20--60 x 3--8 mm, apex

acute, apiculate; petioles 6–20 mm long on lower leaves, 2–3 mm long above; stipules lanceolate, 8–16 x 0.5–2 mm. *Inflorescence* racemose, rarely pseudoumbellate, often lax, 1–7-flowered, terminal, becoming leaf-opposed; peduncle 5–50 mm long; bracts narrowly ovate to lanceolate, 5–8 x 0.5–0.75 mm, bracteoles narrowly ovate to linear, 3–6 mm long. *Calyx* sericeous, deeply bilabiate; upper lip 8.5–11 mm long, lobes 5–6.5 mm long, lower lip 10–12 mm long, lobes 4–5.5 mm. *Corolla* yellow; standard with black flecks in the medial basal region, broadly obdeltoid, 9–12 x 11–13 mm, adaxial surface sparsely sericeous, base canaliculate, claw 2–3 mm long; wings oblong to obovate, 9–11 x 3–6 mm, with lunate-lamellate sculpturing in the basal and upper central zones, claw vertical, 2–2.5 mm long; keel acutely cymbiform, 7–8 x 4–5 mm, claw vertical, 2.5–3 mm long. *Stamens* monadelphous, sheath completely fused above. *Ovary* 4–5 mm long, often laterally glabrous; style 3–4 mm long. *Fruit* sericeous, compressed, only immature fruits seen. *Seed* not seen.⁵²

Herbarium specimens of *A. pseudotuberousum* are easily mistaken for *A. tuberosum* because flower colour is not preserved in pressings. The flower colour of *A. tuberosum* is anomalous within the genus, the adaxial surface of the standard is russet while the abaxial surface is creamy yellow. The wing petals are pale basally

Figure 102

Argyrolobium pseudotuberousum. A. Habit (bar = 20 mm); B. calyx, inner surface (bar = 2 mm); C. keel (bar = 2 mm); D. wing (bar = 2 mm); E. standard abaxial surface (bar = 2 mm); F. standard, lateral view (bar = 2 mm). Voucher: Edwards & Burrow 1019.

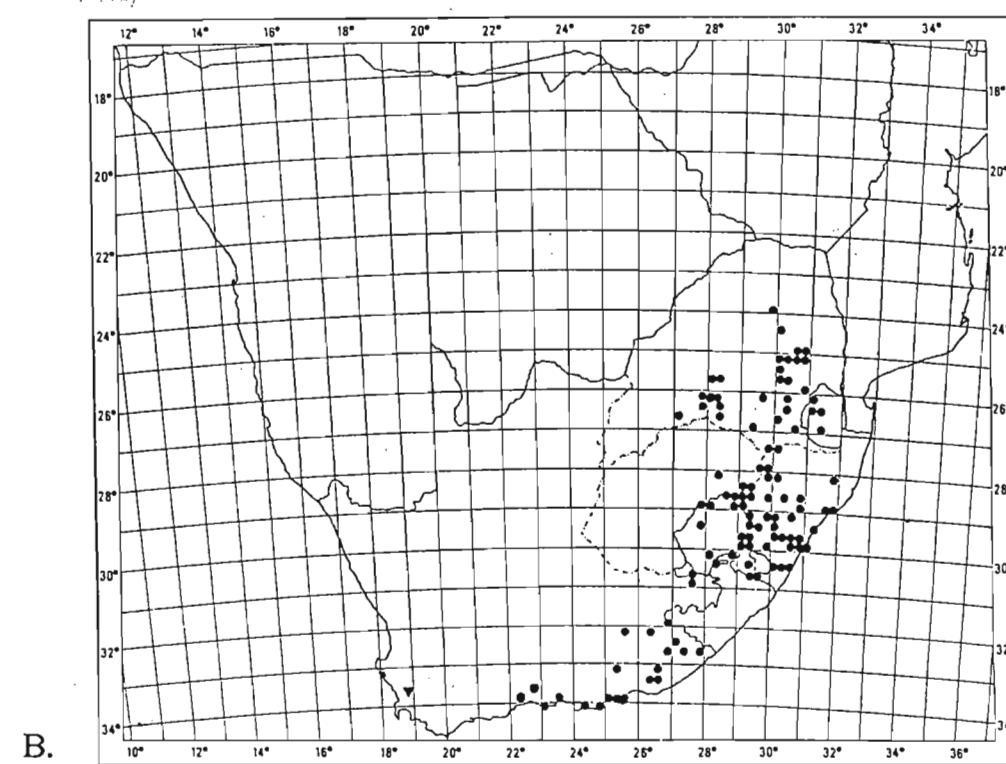

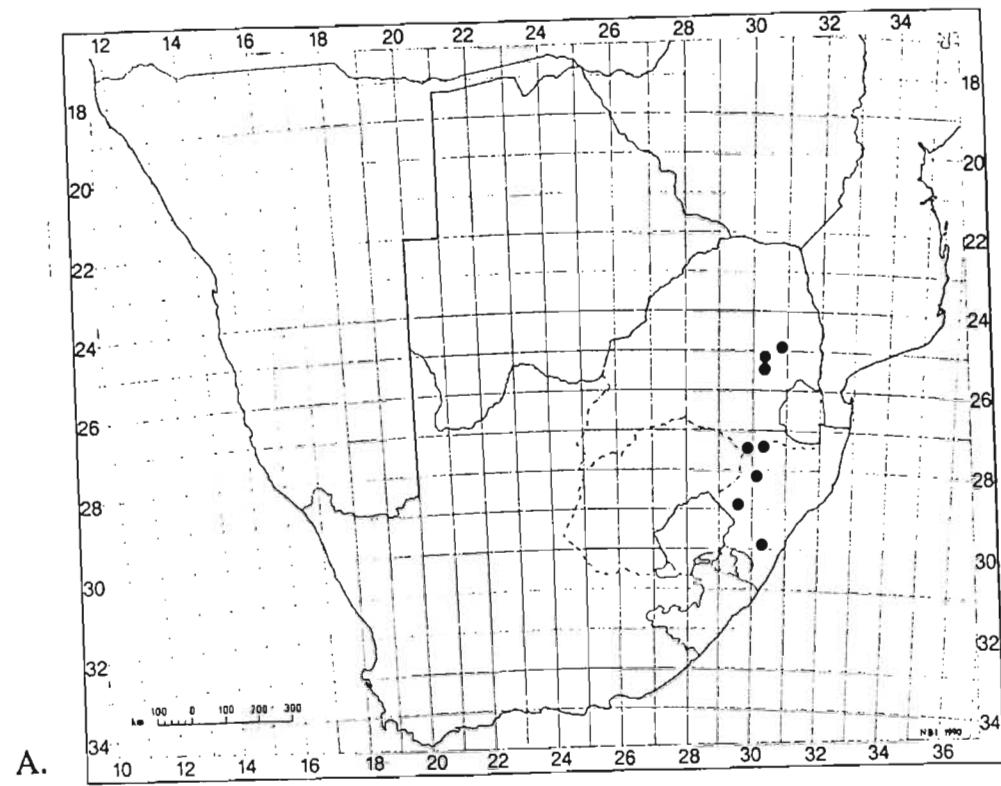

Figure 103. Recorded distribution of A. *A. pseudotuberosum* & B. *A. tuberosum* (●), *A. angustissimum* (▼).

but are russet distally and the keel is creamy yellow. Flowers of *A. pseudotuberosum* are consistently lemon yellow with black flecks medially on the standard. While the distributional range of *A. tuberosum* overlaps with that of this species, mixed populations have never been recorded. All populations of *A. pseudotuberosum* have been recorded from moist grassland, mainly in North-Eastern Mountain Sourveld or Dohne and Highland Sourveld (Figure 103). *A. tuberosum* is common in drier habitats.

41. *Argyrolobium angustissimum* (E. Mey.) T. J. Edwards *stat. nov.* Type:
Cape, Paarlberg, 1000--2000', *Drège s.n.* (G!, lecto. selected here; BM!, E!,

MO!, OXF!, P!, S!, W!, isolecto.).

Chasmone angustissima E. Mey.: 75 (1836). Type: as above.

Herb, 0.2--0.3 m tall, erect, sparsely branched, stems weakly perennial, shortly sericeous, plants solitary, or forming small clumps. *Leaves* adaxially glabrous, abaxially shortly sericeous, linear, 25--45 x 1--1.5 mm, conduplicate, apex acute, petiole 1.5--3 mm long; stipules deltoid to linear, 2--4 x 0.5--1 mm. *Inflorescence* pseudoumbellate, 1--6-flowered, pedunculate, leaf-opposed; bracts linear, 4--5 x 0.75--1 mm; bracteoles linear, 3.5--5 x 0.75 mm. *Calyx* shortly sericeous, upper lip 14--15 mm long, sinus 12--14 mm deep; lower lip 15--17 mm long, lobes 4--5 mm long, medial lobe linear. *Corolla* yellow; standard obovate, 16--18 x 10--12 mm, adaxial surface sparsely sericeous, base cuneate, claw 1--2 mm long; wings narrowly oblong to obovate, 14--15 x 3.5 mm, with lunate-lamellate sculpturing in the upper basal zone, claw 1--1.5 mm long; keel cymbiform, 7--9 x 3.5--5 mm, distally sericeous, claw 1--1.5 mm. *Stamens* monodelphous; anthers very weakly dimorphic. Ovary weakly arcuate, c. 10 mm long, densely sericeous; style 3--4 mm long, basally hairy. *Fruit* not seen. *Seed* not seen.

A. angustissimum is formerly recognised on the basis of its robust habit and large distinctive flowers (Figure 96). It is closely allied to *A. tuberosum* which has similar leaf morphology and flower colour but differs in the size and morphology of the flowers. The species are allopatric and *A. angustissimum* is known from a

single Drège collection (Figure 103). It occurred in Macchia vegetation of the Paarlberg and is probably extinct.

3318 (Cape Town): Paarlberg, (--DB), *Drège s.n.* (E, G, MO, O, P, S).

42. *Argyrolobium tuberosum* Eckl. & Zeyh., Enum. Pl. Afr. Austr. 2: 188 (1836); Walp.: 508 (1839); Walp.: 632 (1843); Meisn.: 73 (1843); Benth.: 341 (1844); Harv.: 69 (1862); Burtt Davy: 393 (1926); Polhill: 152 (1968). Type: eastern Cape; Uitenhage, Krakakamma, *Ecklon & Zeyher* 1322 (B†; K!, lecto. selected here).

A. angustifolium Eckl. & Zeyh.: 188 (1836); Walp.: 506 (1839); Walp.: 630 (1843). Type: Cape Province, Winterberg, *Ecklon & Zeyher s.n.* (B†; TCD!, lecto. selected here).

Chasmone tuberosa Meisn.: 73 (1843). Type: as above.

Argyrolobium woodii Dümmer: 274 (1912), *synon. nov.* Type: Natal, Liddesdale, *Wood* 3937 (K!, lecto. selected here).

Argyrolobium lydenburgense Harms: 183 (1917), *synon. nov.* Type: eastern Transvaal, between Lydenburg and Spitzkop, *Wilms* 291 (BM!, lecto. selected here; E!, G!, isolecto.)

Argyrolobium glaucum Schinz: 225 (1921), *synon. nov.* Type: Transvaal, Elandspruitberg, *Schlechter* 3841 (BOL!, lecto. selected here; B!, BR!, GRA!,

PRE!, isolecto.).

Herb, 0.1--0.7 m tall, erect, sparingly branched, stems weakly perennial, sparsely sericeous, plants solitary. *Leaves* sometimes dimorphic; lower leaflets broadly obovate, elliptic, to narrowly lanceolate, 10--50 x 3--6 mm, shortly pilose to glabrescent, petiole 8--60 mm long; upper leaflets usually conduplicate, linear to oblanceolate, 25--70 x 1.5--6 mm, abaxially sericeous, apex acute, apiculate, petiole 2--15 mm long; stipules subulate below deltate above, 2--15 x 0.5--1 mm.

Inflorescence 2--14-flowered, racemose to pseudoumbellate, leaf-opposed; bracts linear-lanceolate, 2--6 x 0.25--0.5 mm; bracteoles setaceous, up to 3 mm long.

Flowers dimorphic. *Calyx* sericeous, upper lip 6--8 mm long, sinus 3--5 mm deep; lower lip 7--9 mm long, lobes 2--4 mm long, medial lobe linear. *Corolla* russet and lemon yellow; standard suborbicular, 9--15 x 10--15 mm, adaxial surface sparsely sericeous and russet, abaxial surface lemon yellow, base cordate, claw 1--1.5 mm long; wings oblong to narrowly cymbiform, 8--13 x 3--5 mm, proximally lemon yellow distally russet, usually with lunate-lamellate sculpturing in the upper basal and upper central zones, occasionally in the lower basal zone, claw 0.75--1.5 mm long; keel cymbiform, 7--9.5 x 3--5 mm, lemon yellow, claw 1--2.5 mm long. *Stamens* monodelphous split adaxially. *Ovary* narrowly oblong, 6--8 mm long, densely sericeous or laterally glabrous; style 3.5--5 mm long. *Fruit* sericeous, compressed, linear, 25--50 x 2--3 mm, erect. *Seed* orbicular or irregular, 1.5--2 mm.

A. tuberosum is widespread (Figure 103) but easily distinguished from sympatric species by its multi-coloured flowers. There is considerable variation in vegetative and floral characters however we could find no means of discerning more than one species. The flowers of *A. angustissimum* (Figure 97) are similar in colour to those of *A. tuberosum* but differ in size and morphology.
